Well, then, the points we have been trying to emphasize are: *first*, that the treatment of disease is not entirely or mainly an affair of drugs—the administration of medicines is, indeed, only a small part of it; and, *second*, that the administration of medicines is not, or ought not to be, an affair of happy chance, or hap-hazard, or rule of thumb, but ought to be determined by (1) a knowledge of the healthy action of the body, (2) a knowledge of the effects of disease in altering healthy action, (3) a knowledge of the influences that can be brought to bear upon the body in health and their mode of operation, and (4) a knowledge of the means by which the body and its various organs can be influenced in a state of disease. What, then, is meant by the rational employment of drugs will be understood. Let us take an example:—A person is attacked with inflammation of the lungs. The physician knows how the lungs should act in a state of health, this physiology has taught him; his study of pathology—the science of disease—has revealed to him how that action is interfered with by various states of disease, and how the particular kind of disease is determined. His examination of the person has shown him the condition of the affected lung, and he has found that a large part of one lung, let us say, is filled up with the products of inflammation so that it can no longer do its share of the work of introducing oxygen to the blood and removing carbonic acid gas from it. This condition of the lung is such that the blood flows through it with great difficulty, that the heart, which drives the blood through it, has enormously increased labour thrown upon it to carry on the circulation, and, besides, the state of fever, the interference with digestion, caused by the disease, and so on, are producing exhausting effects upon the whole body, and on the heart as part of it. For all these reasons the heart has become enfeebled, is showing signs of tiring, so to speak, is weak and irregular in its action, and the risk exists that the patient will die, not directly because of the inflamed lung, but because the heart will fail altogether, because of the undue strain thrown upon it. In a few days the physician expects that the inflammation will abate, and the lung will begin to clear up, and the strain upon the heart will lessen. Meanwhile, however, it is questionable if the heart can hold out till relief begins. So the physician asks himself what can be done to steady the action of the heart and strengthen its contraction, what can he do to aid it to tide over its time of difficulty. The study of the action of medicines has taught him that a drug, digitalis, diminishes the frequency of the heart's beat and increases its force, and his

knowledge of the diseased state indicates that this is the effect that will prove beneficial. So he orders digitalis. He does not simply order a mixture, containing digitalis, and cause a teaspoonful, or any other quantity to be given, mechanically, every three hours, or four times a day, or whatever it be, but he watches its effects. He finds the heart is a little improved, but not very markedly, so he increases the dose; and after a little time longer, it may be, he increases it still more, till he reaches a dose when the effects he desires are obtained, the heart now beats steadily and firmly. Meanwhile his treatment of the inflammation of the lung goes on. In a few days the lung begins to clear up, the difficulty begins to decrease; he begins now slowly to diminish the digitalis, and at length finding the heart no longer fails, is now no longer oppressed with labour, he can safely stop the digitalis altogether, his timely aid having been sufficient, while the time of undue labour lasted.

This is an illustration of a drug rationally employed. The effect to be produced is understood, a drug which can produce this effect is known, and so the drug is given till the desired result is achieved. Let us take another example of a different kind. A person has, by accident, swallowed a poisonous dose of corrosive sublimate—a salt of mercury. If the drug passes into the circulation and is, by the blood, distributed throughout the body in sufficient quantity, its effects will kill him. Obviously the rational treatment is to get the poison out of the stomach before it has had time to be absorbed in sufficient quantity. So the doctor applies the stomach-pump, empties and washes out the stomach. Perhaps a stomach-pump is not at hand, so he tries to make the stomach empty itself; he excites vomiting by tickling the throat with a feather, or putting the finger down. Some of the poison may still be left in the stomach, adhering to its walls, can he give anything which will prevent the poison passing into the circulation? It can only pass into the blood if it is in a state of solution; if the corrosive sublimate is not dissolved, it cannot gain entrance to the blood, and so will do no harm. Now corrosive sublimate forms with albumin an insoluble substance, albuminate of mercury. White of egg consists chiefly of albumin, so the whites of several eggs are rapidly beaten up in water and given to the person to drink, and thus an antidote to the poison is administered.

Now it is not always possible to make use of drugs because of such well-defined reasons as these. Many medicines are used for particular diseases in which their effects have been proved by experience to be useful, and yet the reason of their usefulness, the exact means by which they are beneficial, are not known. Experience only has taught that they are useful, in certain cases, but the reason of their usefulness remains to be discovered. Whether they relieve, or whether they fail to relieve, no scientific reason is yet forthcoming. In such cases the medicine is said to be given **empirically**, and the treatment is said to be empirical treatment. It is undoubtedly the case that a very large number of the remedies regularly employed, including some of the most useful of the remedies in the hands of the physician, are used because experience has shown their value, although the reason of their usefulness is not at all or not well understood. But physicians do not refuse to order medicines, which have been shown without doubt to be appropriate in certain cases, because they do not yet know how they bring about the desired end. It is, however, the object of the modern science of medicine, bringing chemistry and physiology and pathology to its aid, gradually to reveal more and more clearly how these remedies act, and so to increase the number of the drugs which are employed because their mode of action is well understood, and to diminish the number of drugs which are recommended merely because of the facts of experience. This result the science of medicine is gradually achieving; and year by year drugs are being taken out of the class of those used empirically and added to the number of those used rationally. A most notable illustration of this is found in the well-known medicine quinine. Long ago quinine and Peruvian or cinchona bark, from which quinine is derived, were known to be invaluable medicines in the treatment of fevers, and specially of those—such as ague—dependent upon malaria. The cure of ague was regarded as almost a certainty by the administration of quinine long ago, and as late as 1857, Sir Thomas Watson said of it: "I may observe, however, that this is a remedy to which we could never have been led by any process of reasoning. It is a matter of pure empiricism. We know nothing of the seat or of the essential nature of the disease (ague); we are equally in the dark as to the *modus operandi* of the quina in curing it; yet our knowledge of ague, upon the whole, estimated in reference to its precision and practical bearing, is more satisfactory than of many other complaints, with the seat and nature of which we are much better acquainted. The group of symptoms is so distinct, that we

have no trouble or doubt as to the diagnosis; and experience has taught us a remedy which is all but infallible." This might have been said of quinine up to a much later date. Now, however, physiological investigations have revealed much of the way in which quinine acts in controlling certain kinds of fever, and concerning it we may now be said to have passed beyond the mere stage of experience. How salicine, derived from willow bark, acts so marvellously in rheumatism, diminishing the fever, relieving the pain, and removing the swelling, it is impossible to say, yet experience warrants one in almost asserting that in a few hours acute rheumatic fever will yield to its use.

While this is so, still the object of all those who work in the various departments of medical science is to reduce it more and more to the limits of an exact science, to discover the real nature and ultimate causes of disease, to ascertain the actions of drugs in health and in disease, so that those who practise the art of medicine shall always have well-defined reasons for the employment of all the means of meeting disease, and shall have more and more certainty of successfully combating and overcoming it.

Modes of Administering Medicines.

Medicines produce both what is called a local and a remote effect. That is, they act directly upon the part with which they come into contact, and they also act upon parts distant, usually by passing into the blood and being carried thence to other parts of the body. Sometimes it is only the local effect one wishes to produce, as when carbolic acid or other similar substance is applied to an ulcer to convert it into a healthy sore, sometimes one wishes to get the medicine into the blood only so that it may be carried to the distant organ. The usual way of getting the medicine into the system is by giving it by the mouth. It is then swallowed, and passes into the stomach. From the stomach it is absorbed by the blood-vessels, and thus carried through the whole body in the blood stream. Reaching all parts of the body, it may influence all the tissues and organs, but commonly one or more organ is affected more than others, and a special effect is thus produced. Often there are objections to giving it by the mouth. One may desire to avoid its local action on the walls of the stomach, the irritability of the stomach may be such that the substance is vomited speedily after it is swallowed, and another method of introduction is desirable. In such a case the medicine may be mixed with a solution of some non-irritating material like starch and injected into the bowel, from which it is absorbed and passes into the blood. Or the drug may be dissolved in a few drops of water and injected under the skin. This is called *hypodermic injection* (Greek, *hupo*, under, and *derma*, the skin). The instrument used for the purpose is a hypodermic syringe. It is a small, usually glass, syringe, capable of holding 20 or 30 drops, the barrel of the syringe being marked so that the number of drops injected may be easily known. To the nozzle of the syringe is screwed a long slender needle, with a fine canal running through it, and ending in a sharp point. The solution being sucked up into the syringe, the needle is screwed on; slight pressure on the piston drives the solution along the needle till its canal is filled, then the skin is picked up between finger and thumb and the needle thrust through it. The piston is then pressed till the requisite quantity is injected. On withdrawing the needle one presses over the puncture to prevent escape and gently rubs the skin over the seat of injection to cause the fluid to be diffused through the tissue under the skin, and so ensure it being rapidly picked up by the vessels—blood-vessels and lymphatics. This is one of the quickest ways of procuring the action of a drug, it so rapidly gains entrance to the current of blood. A drug may be rubbed on to the skin, and it will produce an effect not only on the part to which it is applied but also on the system in general, because, if well rubbed in, it gets into the vessels. Occasionally the top skin, or scarf skin, is removed by a blister, and a drug, in powder, sprinkled on the raw surface. Some is absorbed and produces remote effects. Then drugs are sometimes caused to enter the body by inhalation—the drug is disseminated through the atmosphere in vapour, and the vapour being breathed, and the drug getting into the lungs, is absorbed by the vessels of the moist delicate mucous membrane. The drug may be converted into vapour and the naked body exposed to its influence, the arrangement being that described for the vapour bath (p. 738). In such a case it is absorbed by the skin. Medicated bath may be given as a means of introducing the medicine into the body. Finally, the speediest method of all would be to inject the drug directly into the blood by a vein, *intravenous injection*, but this method is seldom employed. The speediest method commonly employed is that by hypodermic injection. A small quantity of the drug, thus given, will act as effectually as a larger dose by the mouth,

for it enters the circulation more quickly, and there is a larger quantity circulating at one time. When the drug is given by the mouth, its absorption from the stomach is so much slower, comparatively speaking, that some of it may be already expelled from the body by way of the kidneys, skin, and lungs, before the last of it is absorbed. Then the juices of the stomach, &c., may so act upon the medicine as greatly to change its nature and prevent its full action being produced, an effect avoided by injection under the skin. Thus everything absorbed from the stomach passes through the liver, and the medicine may be much altered in its course. Therefore, a much smaller dose is given by hypodermic injection than would be given by the mouth or bowel.

Dose of Medicines.—The dose of medicines should be regulated by the body weight, for the same dose administered to a small and a large person will be distributed through a smaller quantity of blood in the small person, and thus each organ of the body will receive a larger share than the corresponding organs in the person of greater size. Women, therefore, require a smaller dose than men, and children than grown persons. Age is regarded as the convenient guide in regulating the dose. One rule for fixing the dose for a certain age is to take the age in years of the person, add to it 12, and with the sum divide the age in years, the result expresses the fraction of the full dose to be given. Thus a child's age is 4 years, 4 added to 12 makes 16. Divide the age in years by 16—$\frac{4}{16}$th is the fraction of the full dose for a child of 4 years. $\frac{4}{16} = \frac{1}{4}$, and if the full dose is 4 grains, the child should get 1 grain. The following table may be taken as a guide:—

A child under 1 year	will require only	$\frac{1}{12}$	part of the full dose.
,, 2 years	,,	$\frac{1}{8}$	,,
,, 3 ,,	,,	$\frac{1}{6}$	,,
,, 4 ,,	,,	$\frac{1}{4}$	,,
,, 7 ,,	,,	$\frac{1}{3}$	,,
,, 14 ,,	,,	$\frac{1}{2}$	,,
A young person under 20	,,	$\frac{2}{3}$	,,

A person above 21 receives the full dose.
After 65 years of age the dose is diminished.

It may further be noted that young persons are much more susceptible to the action of certain drugs than are old persons. For instance, children are peculiarly strongly affected by opium, or any of its preparations, such as laudanum, and to them it cannot, therefore, be given too carefully. On the other hand children are *less* affected by preparations of mercury than are adults; and there are instances on record of calomel, a preparation of mercury, having most serious effects on an adult, when given in a dose which almost the youngest child could stand. Another drug to which children are less susceptible than adults is belladonna.

Besides all this, custom, temperament, the influence of climate, and personal peculiarities affect the question. Many people are peculiarly affected by certain drugs, even as many are peculiarly affected by certain foods, while others are hardly influenced at all except with large doses. Opium and mercury are notable illustrations; the smallest doses of these being scarcely tolerated at all by many persons.

We shall now proceed to consider some of the chief remedies and means of treatment in their effects upon the body, and their use in disease, considering them as far as possible according to the organs of the body they chiefly influence.

SECTION I.—MEDICINES WHICH ACT UPON THE BLOOD AND WHICH AFFECT THE NUTRITION OF THE WHOLE BODY.

Medicines which Act upon the Blood.

Blood Tonics:

Iron—Its Preparations and their Doses—Tincture of Steel, Iodide of Iron, Chemical Food, Blaud's Pill, &c.—Its Action and Uses in various Diseases.

Medicines which Increase or Diminish the Alkalinity of the Blood:

Potash—Its Preparations and their Doses—Carbonate and Citrate of Potash, &c.—The Use of Potash in Rheumatism, Gout, and Gravel;

Soda—Bicarbonate of Soda and Rochelle Salts;

Lithia—Its Use in Gout.

Remedies which Cool the Blood—Antipyretics:

Quinine and Peruvian Bark—The Varieties of Cinchona Barks—The Preparations of Bark —The Preparations of Quinine—The Use of Quinine as a Tonic, for Fever and Ague, and as a Disinfectant—Warburg's Tincture;

Salicine—Its Use in Rheumatism;

Salicylic Acid and Salicylate of Soda;

Antipyrin—Its Employment for Fever, and its Use for Nervous Headache;

Thallin, *Antifebrin*, and *Kairin*.

Medicines which Act on Tissue Change.

Alteratives:

Arsenic—Its Chief Preparations—Precautions in its Use—Arsenical Poisoning—Its Use in Skin Diseases;

Mercury—Its Compounds, Action, and Value—Mercurial Poisoning;

Iodine and Its Use in Scrofula and Gland Diseases;

Phosphorus and Its Preparations;

Sulphur—Its Use in Liver Disorders and Skin Affections—Sulphuretted Hydrogen Treatment in Consumption;

Sarsaparilla;

Colchicum—Its Employment in Gout;

Guaiacum—How applied for Sore Throat and Rheumatism;

Mezereum Bark.

In the first part of this work we have considered the characters and composition of the blood (see p. 212); we have considered also the part which the blood plays in the body. We have seen that the whole body, and every part of the body, are dependent upon the blood for the material for their healthy growth and for the material for their healthy activity. The blood is the nourishing fluid of the body, containing within itself all the materials for the building up of every tissue, muscle, nerve, bone, skin, and so on, for the production of every juice required in the body, the digestive juices for example, and for the repair of all tear and wear, continually going on. It is distributed to every organ, and brought within reach of every tissue; and the tissues possess the power of selecting from it the constituents they require for their continued healthy existence. We have considered also how the blood, thus continually being drained of its nourishing materials, is as continually restored to a healthy standard and maintained in a condition fit for the purpose it has to serve. The means for this purpose are mainly food and drink introduced by the mouth and prepared for entering the blood by the digestive organs, and oxygen gas, which the blood obtains through the instrumentality of the lungs. Our earlier studies have also shown us that the blood is, besides, a means of removing from tissues and organs the waste products, due to the activity of the organs and tissues, and how the liver, the bowels, the lungs, the kidneys and the skin, act in ridding the blood of these waste substances and thus maintaining its standard of purity. Through the blood, then, the condition of the whole body may be influenced. If it is impoverished or impure, the organs and tissues will not derive the needed nourishment; or some organs may obtain a fair supply and others may feel the impoverishment more; or along with the needed material for growth and work may also be obtained, because of the impurity, something hurtful to the healthy action of the organ or tissue. If some additional substance be taken into the stomach, which is

able to pass into the blood, it will be carried to all parts of the body. If it is an active substance it may affect more or less every organ and tissue of the body, or it may be of a character fitted to act upon one organ more than another, and may profoundly affect the whole body by its universal action or by specially influencing one or two organs in partcular.

Thus, then, it is plain there are two great ways of influencing the nutrition of the whole body in general: (1) either by acting directly on the blood, or (2) by introducing something into the blood which shall be conveyed by it to all parts of the body and shall modify the action of the tissues when it arrives there. To the first class of remedies belong **blood tonics**, of which the conspicuous example is iron; while the second class is called **alteratives**, that is, they alter or modify the changes going on in the tissues, though how they do so is not well understood, and to that class arsenic, mercury, iodine, and others to be named later, belong.

MEDICINES WHICH ACT ON THE BLOOD.

The blood (see p. 216) consists of minute bodies, corpuscles, red and white, floating in a fluid, liquor sanguinis or plasma. Now the red corpuscles are formed of an albuminous body, hæmoglobin, which contains iron, and they also contain salts of potash and phosphorus, and fat. These red corpuscles give the colour to the blood, and if they are deficient in number, the paleness of the skin is marked, and a condition of bloodlessness, or anæmia, is the result. By supplying to the blood iron, fat, potash salts, the constituents of the corpuscles, much can be done to remedy this condition, supposing, of course, that at the same time appropriate food is given, and fresh air and sunlight and exercise are not forgotten. Then, again, the liquid of the blood contains albumin, soda salts, fat, &c., and by a due supply of these substances an improved condition may be brought about. Because of the soda and potash salts of the liquid and red corpuscles of the blood the blood is not acid but alkaline, and in certain diseases, notably rheumatism and gout, the alkalinity is diminished. By administering soda or potash salts it can be increased, and this is actually part of the treatment in the diseases named. Again, scurvy, a disease in which the nutrition of the whole body is profoundly impaired, is believed to be due to the absence from the blood, or deficiency, of some of its constituents, perhaps potash salts, to be remedied by giving fresh meats and vegetables which contain the salts, or by the use of lime-juice.

Thus we see how the condition of the blood can be influenced by the administration of substances which are needed for its formation and which otherwise act upon it directly, and how in consequence the nutrition of the whole body may be improved.

Then, again, the red corpuscles, because of the hæmoglobin of which they are mainly composed, act as the distributors of oxygen gas to the tissues, without which their activity cannot be carried on. The hæmoglobin forms a loose chemical compound with oxygen, and when the blood obtains the oxygen in the lungs, it is forthwith carried to the tissues and delivered up to them, so to speak. If the corpuscles are deficient, then oxygen in sufficient amount cannot readily be carried to the tissues. They cannot carry on their processes with ordinary activity, and all the energies of the body become, in consequence, diminished; the patient is weak, languid, dull, sleepy; and the heart is greatly quickened and the breathing hurried with the least exertion, perhaps in the attempt to make up for the defective oxygen-carrying capacity of the blood by increasing the rate of its distribution through the body, that is to say, by making the corpuscles travel all the oftener between the lungs and the tissues. By the administration of iron with appropriate food, &c., the multiplication of red blood corpuscles is encouraged, and relief in time obtained.

Now there are drugs which interfere with the yielding up of oxygen to the tissues by the red corpuscles. The corpuscles duly bring their load of oxygen, but are prevented handing it over, so to speak. This is an effect which is produced by alcohol, and is also produced by quinine. It is an effect which one would not seek to produce in health, but is often exceedingly valuable in disease. For instance, in fever the heat of the body is greatly increased, owing, in certain fevers at any rate, to too great *production* of heat in the body. We know that heat in the body is produced in the same way as heat outside of the body is produced (see p. 527), by a union of certain substances, carbon and hydrogen, with oxygen. The substances that unite with the oxygen are in the tissues, and the oxygen, as we have said, is brought to them by the blood. If the oxygen is so firmly united to the corpuscles that it is given off from them with difficulty, the chemical combination will be diminished and less heat will be pro-

duced. This is the effect of quinine, and thus in cases of fever it diminishes the heat of the body by lessening the production of heat, by preventing the corpuscles giving up their oxygen so quickly as they would otherwise do.

The general action of remedies on the blood having thus been briefly indicated, we shall now shortly note the chief points of importance connected with the drugs.

Blood Tonics.

Blood Tonics are remedies which improve the quality of the blood by supplying materials in which it is deficient. The chief of them are also called **hæmatinics,** because they increase the quantity of colouring matter in the blood.

Iron in some form is the chief blood tonic. The chief preparations of iron in common use and their doses are as follows:—

	DOSE.
Reduced Iron	2 to 6 grains.
Saccharated Carbonate of Iron	5 to 20 ,,
Sulphate of Iron	1 ,, 5 ,,
Dried Sulphate of Iron	½ ,, 3 ,,
Phosphate of Iron	5 ,, 10 ,,
Syrup of Phosphate of Iron	60 drops.
Tincture of Steel (Tincture of Perchloride of Iron—Steel Drops)	10 to 40 drops.
Dialysed Iron	10 ,, 30 ,,
Iron Wine	1 to 4 tea-spoonfuls.
Tartrate of Iron (Potassic Tartrate of Iron)	5 to 20 grains.
Citrate of Iron and Ammonia	5 ,, 10 ,,
Citrate of Iron and Quinine	5 ,, 20 ,,
Iodide of Iron	1 ,, 5 ,,
Syrup of Iodide of Iron	20 to 60 drops.
Arseniate of Iron	$\frac{1}{16}$ to ⅛ grain.

Griffith's Mixture (compound mixture of iron) is a favourite iron mixture, containing sulphate of iron (25 grains), carbonate of potash (30 grains), powdered myrrh (30 grains), spirit of nutmeg (½ oz.), sugar (60 grains), and rose-water (9 fluid ounces). Dose—1 to 2 fluid ounces.

The myrrh, spirit of nutmeg, and carbonate of potash are rubbed up together in a mortar, then the rose-water is added and well mixed, then the sugar, and lastly the sulphate of iron. It should be kept in a stoppered glass vessel.

Parrish's Syrup or Chemical Food is another favourite remedy, containing phosphate of iron, with the phosphates of lime, potash, and soda, dissolved in dilute phosphoric acid and sugar added. Dose—1 tea-spoonful.

Easton's Syrup is a syrup containing phosphate of iron with the phosphates of quinine and strychnine. Dose—½ to 1 tea-spoonful.

Syrup of the Hypophosphites contains iron, lime, potash, soda, &c., as well as other ingredients like quinine and strychnine. Dose—½ to 1 tea-spoonful.

Blaud's Pill contains sulphate of iron and carbonate of potash. In the stomach carbonate of iron is formed. It is a very good form for the administration of iron.

Action and Uses of Iron.—The preparations of iron have an effect upon the tissues with which they come into contact before they enter the blood. Thus the astringency of most of the preparations is perceived by the action on the mouth. They discolour the teeth, and thus when not given in the form of pill, but as a liquid, they should be taken through a glass-tube, a straw even would suit the purpose, and the mouth and teeth should be well washed afterwards. They exert a constringing effect upon the lining membrane of the throat, gullet, stomach, and bowels. They cause blood to contract and form a clot with albuminous bodies, such as blood. Now this purely local action is often useful, and they are, therefore, used to diminish discharge from organs, to arrest bleeding, and for similar purposes. Thus, besides being given by the mouth to produce such local effects on the mouth or throat, stomach or bowels, they are employed as injections, in cases of bleeding from the nose, bleeding from gums, from leech-bites, &c. In some of the preparations these effects are specially marked, the tincture of steel and sulphate of iron, for example. It is the same action which makes iron preparations valuable in cases of relaxed bowel, diarrhœa, and so on. The astringency, however, causes iron to be badly borne by many persons, persons with irritable stomach for example, and is disadvantageous in cases where there is no looseness of bowels, from the tendency to cause constipation. It is, therefore, common to combine with the preparation of iron some substance which will have an opening effect. Thus the iron-and-aloes pill acts upon the lower bowel, securing a movement, while the benefits of the action of iron are also obtained. It must be noticed also, that iron preparations colour the motions black, owing to the formation in the bowel of the black sulphide of iron.

In cases where the local action is not specially desired, one seeks to make use of those forms of the remedy which have the least constringing action, since this effect is apt to irritate the stomach and bowels. If the person has a red, raw-looking tongue, this is held to indicate an irritable condition of stomach, when iron would not be given, or only in the mildest form in

small doses. When the tongue is pale, flabby, and shows the marks of the teeth on the edge, iron is suitable. The least astringent forms are the reduced iron and dialysed iron specially, the saccharated carbonate of iron, the phosphate, tartrate, and citrates of iron, and the hypophosphite.

The direct action of iron on the red corpuscles is the peculiarly valuable effect for which iron is most usually administered, its effect upon the organs and tissues being practically none, except through the improved quality of the blood which it produces. It is thus the most useful drug in bloodlessness (anæmia), in all conditions of impaired nutrition, in cases of wasting due to loss of blood or chronic discharges, in the condition of weakness following fevers, in scrofula, in malarial poisoning, in blood poisoning, in diphtheria, erysipelas, &c. For the two last-named diseases it is given in large doses, the tincture of steel being very useful in 10-drop doses given in water five times a day, or the dialysed iron. The carbonate of iron, Griffith's mixture, Blaud's pill, and the syrups of the phosphates or hypophosphites are also the most serviceable. In chronic kidney disease it is also used. In nervous diseases, and in the flushings experienced at the change of life, any of such preparations is most valuable. In nervous cases the combinations with strychnine, such as in the compound syrup of hypophosphites or Easton's syrup, are those to be employed.

The citrates of iron are the mildest preparations, and may be given when it is doubtful if other forms will be well borne.

In cases of deficiency of the menstrual flow the carbonate of iron and Blaud's pill are commonly employed.

The combination of iron with iodine, and specially the syrup iodide of iron, is one of the most valuable remedies for scrofula and affections of glands; and there is scarcely a better remedy than this for the pale, flabby, unhealthy children of towns, given to the extent of 15 drops or thereby, dropped into a teaspoonful of cod-liver oil, three times daily. Nervous diseases of children derive great benefit in many cases from such treatment. The syrup of the phosphate of iron is suitable for rickety children.

The compound of iron and arsenic is useful for skin affections in pale persons, and for other anæmic conditions, but it ought scarcely to be used without proper advice.

Iron is an antidote, in one of its forms, to poisoning by arsenic. The form used is the hydrated oxide, when freshly prepared, by adding a solution of soda or ammonia to the tincture of perchloride of iron in water, or to a solution of the sulphate of iron. It forms with the arsenic an insoluble compound. A brisk purgative should afterwards be given.

Medicines which Increase or Diminish the Alkalinity of the Blood.

The chief remedies which increase the alkaline character of the blood are potash, soda, magnesia, lime, and lithia.

Potash.—The chief preparations of potash are as follows:—

	DOSE.
Carbonate of Potash	10 to 30 grains.
Bicarbonate of Potash	10 ,, 40 ,,
Solution of Potash (Liquor Potassæ)	15 ,, 60 drops in a wine-glassful of water.
Iodide of Potassium (see p. 825)	2 to 10 grains.
Bromide of Potassium (See under Drugs which Act on the Nervous System.)	5 ,, 30 ,,
Citrate of Potash	20 ,, 60 ,,
Acetate of Potash	10 ,, 60 ,,
Nitrate of Potash	10 ,, 30 ,,
Chlorate of Potash	10 ,, 30 ,,
Acid Tartrate of Potash (Cream of Tartar)	60 grains and upwards.

Actions and Uses of Potash.—This remedy produces very different effects according to the form in which it is used, and acts on many organs, according to the dose given. Thus caustic potash, usually in the form of white pencils, is employed for its destructive action on the tissues to destroy unhealthy ulcers, remove tumours, &c. Then potash is employed for its chemical antagonism to acid, being given to neutralize acidity of the stomach as soda is given. For this purpose the bicarbonate is the best. The solution of caustic potash (liquor potassæ) is also employed, but it requires to be largely diluted; it cannot be taken to any extent because of its corrosive action; and is not to be recommended. Then the action of the bromide and iodide of potassium depends chiefly on the bromine and iodine in combination, and these substances are discussed elsewhere. The carbonate, bicarbonate, tartrate and acid tartrate act in large doses on the bowels, producing copious watery stools. This action is referred to in considering the drugs acting on the bowels. Again, the citrate, acetate, and nitrate act specially on the kidneys and are, therefore, considered in the section devoted to drugs which act on the kidneys.

It is the action of potash on the blood that

is to be mainly noted here. It readily gains entrance to the blood, increasing its alkaline reaction. Then the red corpuscles contain potash salts, and in disordered conditions of blood the use of potash, *in combination with iron*, greatly improves the quality of the blood by increasing the number of red corpuscles. For this purpose the best form is Blaud's pill (see p. 817) or the compound iron mixture (see p. 817). Potash is used by itself in diseases supposed to be due to an excessive amount of acid in the blood, such as rheumatism and gout. For this purpose the bicarbonate, the citrates, acetates, and tartrates are employed. Nitrate of potash—saltpetre—is an old remedy, in high repute, for rheumatism. These drugs, after passing into the blood, where they are mostly converted into carbonates, are excreted by the urine, the acidity of which they diminish, or, if in sufficient quantity, altogether remove. They are, therefore, valuable for relieving the scalding due to the irritating effect of excessively acid urine, and to prevent the formation of stone by the deposit of uric acid. Then in being excreted by the kidneys they so act upon them as to produce a greatly increased flow of urine. Owing to the increased separation of water from the blood, dropsies of various kinds are diminished, because the fluid of the dropsy is picked up to restore to the blood its normal quantity of water. The citrate of potash is useful as a preventive of scurvy.

The chlorate of potash is principally used for its local action on ulcers, thrush, and other similar affections of the mouth, throat, stomach, &c. It very speedily exerts a cleansing and healing action on the lining membrane of the mouth and throat affected by patches of ulceration, &c. It is, therefore, used in these conditions and in cases of relaxed throat, in diphtheria, &c. A very convenient form of administration is the pellets, containing 5 grains each, now to be had of nearly every druggist, and the chlorate of potash pastilles. It is said, also, when it gains entrance to the blood, to give up some of the oxygen, in which it is rich, and thus act upon the blood after the manner of a disinfectant in cases of diphtheria, blood-poisoning, &c.

Soda.—The chief preparations of soda are:

	DOSE.
Carbonate of Soda	5 to 30 grains.
Bicarbonate of Soda	10 ,, 60 ,,
Tartrate of Soda and Potash (Rochelle Salts)	¼ ,, ½ ounce.
Phosphate of Soda	¼ ,, 1 ,,
Borax (Biborate of Soda)	5 ,, 40 grains.
Hyposulphite of Soda (see Section III.).	

Soda in the form of chloride of sodium or common salt is present in all the tissues and fluids of the body, and is introduced with all foods, existing as it does in them as part of their constitution, and being commonly added to many as a matter of taste. Perhaps it is on this account that soda does not have any peculiar action on any organ or tissue of the body.

What has been said of the salts of potash is true of those of soda, only to a less marked extent. Soda passes into the blood much less quickly than potash, and is on that account less used for its direct action on the blood, and more used for its action on the stomach and bowels, in cases of acidity and heartburn, &c. (see Section III.), though it may be employed in such cases as the potash preparations are used for. The bicarbonate is the preparation in most use. The phosphate and hypophosphite of soda are found in the compound syrups of hypophosphites because of their value in general nutrition.

Lithia.

Carbonate of Lithia	Dose, 3 to 6 grains.
Citrate of Lithia	,, 5 ,, 10 ,,

Lithia increases the alkaline character of the blood like soda and potash. Its special property, however, is the readiness with which the compounds it forms with uric acid dissolve. Now, excess of uric acid in the blood is supposed to be the cause of gout, and lithia is, therefore, given to ward off a threatened attack by removing the uric acid by the way of the kidneys, and to relieve an attack already begun. Deposits of uric acid in the kidney and bladder produce gravel—stone—and so lithia is given to dissolve the deposits and prevent the accumulation ever reaching the actual proportions of stone.

Magnesia and lime belong to the same class of remedies as potash, soda, and lithia, but as they are mainly used for their action on the digestive organs, they are noted in the section devoted to a consideration of the remedies that act on the digestive system.

As the natural alkaline character of the blood is increased by the use of potash, &c., so it might be to some extent diminished by the use of acids. They are not usually employed, however, to produce this effect, and they will be more suitably considered in the section on remedies acting on the digestive system.

Remedies which Cool the Blood—Antipyretics.

We are using rather a rough phrase when we speak of remedies which cool the blood, but the

sense in which it will be understood is sufficiently accurate. We take quinine as the type of these substances, and it has been already pointed out that quinine prevents the ready yielding up by the blood corpuscles of oxygen to the tissues, and so diminishes the process by which heat is produced, and thus actually a cooling action results. This effect is chiefly obtained when the heat of the body is above the proper standard, when fever is present. Substances which diminish fever are called **antipyretics**, from the Greek *anti*, against, and *puretos*, fever. **Antifebrile** is a word with a similar meaning, and **febrifuge** also. Another word applied to medicines used for a like purpose is **antiphlogostic**, from the Greek, *anti*, and *phlogōsis*, burning heat. Besides quinine, there are several other substances which diminish fever—salicine, antipyrin, antifebrin, kairin, &c., although the manner in which they act is not well understood. Besides the administration of such drugs, there are other means of lowering the temperature of the body, which will, therefore, be rightly counted as means of antipyretic treatment. Chief of these is the use of the cold bath, which acts by the direct abstraction of heat from the body. Other methods consist in acting upon the skin, so that the blood-vessels of the skin are dilated, more blood comes to the surface, it becomes thereby cooled, and the skin glands become more active, the increased perspiration which results leading to increased loss of heat. This effect is produced by alcohol and by digitalis. Then the kidneys may be stimulated to separate more urine, and thus increase the loss. While numerous other substances, such as aconite, veratrum, and so on, so depress the activity of the tissues that less heat is produced, and the rate of loss remaining the same, the body becomes cooled.

In this section we propose to consider only a few drugs, such as quinine, salicine, and antipyrin, which speedily lower fever heat in a special way not yet well understood. It is to be noted that these drugs, while they reduce or remove fever, have usually no effect upon the natural temperature of the healthy body.

Quinine is obtained from the bark of the cinchona tree, found in Peru, Bolivia, and Columbia, growing on the Andes, chiefly on the eastern face of the Cordilleras, at a height of from 4000 to 12,000 feet above the sea-level. The trees are now successfully cultivated in India, Java, Ceylon, and Jamaica. There are three chief kinds of cinchona, the pale cinchona, the yellow cinchona, and the red cinchona. The yellow cinchona (*Cinchona Calisaya*) is the richest in quinine, the red bark (*Cinchona succirubra*) contains it also, but the pale cinchona (*Cinchona Condaminea*) yields chiefly a substance called **cinchonine**, whose properties resemble those of quinine.

The Yellow Cinchona bark is the most important. It is obtained in quills or flat pieces of a tawny yellow colour. Reduced to powder it is sold under the common name **Peruvian Bark**, of cinnamon-brown colour, aromatic and bitter taste. The powder is not now much employed. The dose is 20 to 60 grains or more, but it contains tannin, and therefore produces an astringent action, and much of it is useless woody fibre. Moreover it is not so readily tolerated by the stomach, and since the desired effects can be got out of a very much smaller dose of quinine, the powdered bark is little employed.

Its preparations are:—

	DOSE.
Decoction of Yellow Bark.........	1 to 2 fluid ounces.
Liquid Extract of Yellow Bark...	10 ,, 30 drops.
Infusion of Yellow Bark...........	1 ,, 2 fluid ounces.
Tincture of Yellow Bark..........	½ ,, 2 tea-spoonfuls.

The Pale Cinchona occurs in quills, with a whitish, yellowish-white, or ash-gray coating. Its powder is pale brown. Its only preparation is:

Compound Tincture of Pale Bark....Dose, ½ to 2 tea-spoonfuls.

Besides bark, the tincture is made of bitter-orange peel, serpentary, saffron, cochineal, macerated in proof spirit.

The Red Cinchona is found in flat pieces, less frequently in quills, reddish-brown on the outer surface; its powder is red-brown. Tincture, liquid extract, &c., may be made of it, as of the yellow bark, the doses being the same. Tincture of the red cinchona bark has been very highly recommended in America to allay the craving for drink in habitual drunkards. It is given in tea-spoonful doses (see p. 105).

The cinchona barks contain four highly complex chemical substances, called alkaloids, namely quinine, quinidine, cinchonine, and cinchonidine; they also contain acids and a volatile oil.

Quinine is obtained from the bark by maceration with weak hydrochloric acid, and then adding a solution of soda, which precipitates it. The powder is then washed, dissolved by dilute sulphuric acid, and allowed to crystallize out of the solution, so that it is the sulphate of quinine that is usually obtained.

Its preparations are as follows:—

Tincture of quinine................Dose, 1 tea-spoonful and upwards.
(Each tea-spoonful contains 1 grain.)

Quinine Wine....Dose, 2 table-spoonfuls and upwards.
(Made with 1 pint of orange wine, 20 grains of quinine, and 30 grains of citric acid. An ounce, or two table-spoonfuls, contain 1 grain.)

Quinine Pill..................Dose, 3 grains and upwards.
(Each 3-grain pill contains 1 grain of quinine.)

Actions and Uses of Quinine.—Quinine acts on the stomach as a bitter tonic, when taken in small doses (½ to 1 grain), aiding the appetite and digestion, and being thus useful in states of general weakness, and in convalescence from acute disease. In large doses it may irritate the stomach and cause loss of appetite and sickness. It is its action on the blood with which we are here concerned, which, as already described, chiefly consists in binding the oxygen more firmly to the red blood corpuscles, and so preventing oxidation changes in the tissues, and lowering the heat of fever. For this purpose it requires to be given in large doses, 5 or 10 grains or even more, repeated if necessary. Such large doses produce peculiar effects on the nervous system, singing in the ears, deafness, a feeling of tightness in the head, giddiness, sometimes headache, and impairment of sight. By very large doses delirium is produced, and death might be caused, sometimes with convulsions. To these effects the term **quinism** or **cinchonism** is applied. In large doses quinine also weakens the heart, and slows the breathing. It is expelled from the body by the urine, and may irritate the bladder and urinary passage. It may stimulate the pregnant womb, and should, therefore, be given cautiously in this condition, lest miscarriage result.

Its most valuable effects are produced in such fevers as ague, and malarial fevers of all kinds, and in typhus fever, enteric fever, and fever due to blood-poisoning of other kinds. For ague, as a preventive, it is given in doses of 3 or 4 grains three times a-day, or, just before a fit is due, a single dose of 10 grains is best. For other fevers a single large dose may be given (10 grains or more) and repeated once in twenty-four hours, only if necessary, or two smaller doses (5 grains) may be given within one hour.

The influence which it has on fevers, recurring at definite periods—its **anti-periodic** effect, as it is called—extends also to other periodic affections, such as a neuralgia which tends to recur daily at a particular time. This may often be prevented by giving a 5-grain dose an hour or so before the usual hour of attack. Neuralgic headache it relieves, and with all the more certainty if it is combined with 20 grains of salicine.

Quinine, by a similar action to that which it exerts in preventing oxidation, prevents also fermentation, and it thus acts as an antiseptic, preventing the growth of minute organisms. Thus a dilute solution will preserve meat, milk, &c., for a length of time. On this account it is used as a gargle for ulcerated sore throat, and is added to tooth-powders.

The other substances named, cinchonine, &c., have similar effects but to a less extent.

Warburg's Tincture contains quinine with aloes, opium, rhubarb, camphor, and a number of aromatics, and is used for ague in doses of from one to four tea-spoonfuls.

Salicine is derived from the bark of the willow. It is also contained in poplar bark and in flower-buds of meadow-sweet.

Action and Use.—It reduces fever, and is specially employed in the treatment of rheumatic fever, being given in doses of 20 grains, repeated every two hours, till the fever abates and the pains disappear. When this has been accomplished, a powder should be given four times daily for several days to prevent a return of the attack. It is also very useful for neuralgia and neuralgic headaches, especially when combined with 5 grains of quinine.

Salicylic Acid may be derived from the oils of winter-green or sweet birch, but is usually derived from carbolic acid by heating with caustic soda and passing through it a stream of carbonic acid. It can also be obtained from salicine.

Its Actions and Uses resemble very much those of quinine. Thus, like the latter, it prevents putrefaction and decomposition, and is used largely for surgical dressings, for impregnating wool for surgical purposes. A mixture of 2 parts in 100 of tallow applied to the skin of the feet is useful in preventing sweating and soreness of the feet by walking. It is also employed as a lotion—4 parts to 100 of water—in irritation of the skin. Its internal effects are also like those of quinine, and produce like it noises in the ears, deafness, headache, and in large doses delirium. Like salicine it is used in acute and chronic rheumatism in doses of from 5 to 30 grains. But commonly a salt prepared from it, salicylate of sodium, is preferred.

Salicylate of Sodium..................Dose, 20 grains.
Used in the same way as Salicine.

Antipyrin is one of the most recent of the

antipyretic class of drugs. It is a patented preparation, made in Germany.

Action and Use.—It causes profuse perspiration, and in suitable cases reduces fever with great rapidity. For adults the full dose is 30 grains hourly for three hours, but it may be given in smaller doses—10 grains—every half-hour, when the desired effect will usually be obtained after three or four doses, and further administration is withheld till the fever again threatens to rise, when the same process is repeated. It has a sweetish-bitter, peculiar, but not unpleasant taste, and requires a good quantity of water to dissolve it. In typhoid fever, and in blood-poisoning, in scarlet fever and other fevers, it is particularly serviceable, and it may be given to children in almost any feverish complaint, to the extent of $1\frac{1}{2}$ grain for every year of the child's age, every hour for three hours. It may be sweetened for them. In the author's experience it is not so serviceable in reducing fever resulting from inflammation, such as inflammation of the lungs, inflamed tonsils, and the like. The influence of antipyrin on nervous headache is most surprising. The true nervous headache—megrim—will almost certainly be relieved within twenty minutes or half an hour by a dose of 10 or 15 grains. The person, after taking this dose, should if possible lie down in a quiet room. If relief is not begun, or is only slight, in twenty minutes, let a second dose be taken, and a third within other twenty minutes, if needful, and still a fourth, if required. If, however, these four doses fail to relieve, there is little use continuing the drug. In this drug, however, the person subject to periodic nervous headache, brought on also by the least excitement, shopping expeditions, &c., possesses a medicine that, in the author's experience, very rarely fails.

Thallin, used for fever in 5-grain doses, does not appear to be so good as antipyrin.

Antifebrin reduces fever quickly, and maintains the lower temperature for from three to seven hours, according to the quantity given. The dose is from 4 to 15 grains, not more than 30 grains being given in twenty-four hours. It slows the pulse, and often causes the patient to fall into a quiet sleep. In fevers generally, and specially in typhoid fever, rheumatic fever, and erysipelas, it is employed.

Kairin has a marked effect on fever, given in doses of from 3 to 30 grains. It is recommended that doses of 8 grains should be given every hour for four times or till the temperature has fallen to 100° Fahr. If the four doses have thus reduced the fever, 4 grains should be given every hour, should it appear necessary, but if the fever again rises, the larger dose is again given. It produces great sweating.

MEDICINES WHICH ACT ON TISSUE CHANGE.

Alteratives.

Alteratives, as already explained (p. 816), is the term applied to the drugs we are now about to consider, which improve the nutrition of the body by altering or modifying the chemical processes going on within the tissues, without producing any very perceptible action upon any organ or tissue in particular. The chief of these drugs are the metals, arsenic, mercury, iodine, and phosphorus, sulphur, and certain vegetable drugs, sarsaparilla, colchicum, guaiacum, &c. How these remedies act is not understood. They act slowly, without any apparent influence on the circulation, on the breathing, &c., and yet in time their effects appear. Their influence is brought to bear in the region of minute chemical change, at present beyond the reach of accurate scientific investigation. In time, however, the fact that they operate specially upon particular organs, though their modes of acting on these organs is unknown, becomes apparent. Thus arsenic specially influences the nutrition of the skin, mercury and iodine act specially upon glands and upon the nervous system, and so on.

Arsenic.—The chief preparations of arsenic are as follows:—

	DOSE.
Arsenious Acid (White Arsenic).....	$\frac{1}{60}$th to $\frac{1}{24}$th grain.
Liquor Arsenicalis (Fowler's Solution)	2 to 5 drops.
Arseniate of Iron........................	$\frac{1}{16}$th to $\frac{1}{8}$th grain.
Donovan's Solution (Solution of Arsenic, Iodine, and Mercury)...	10 to 30 drops.

Precautions in the Use of Arsenic it will be well to note first. As everyone knows arsenic is a powerful poison. Two grains of metallic arsenic have proved fatal, even when their administration was prolonged over five days. This quantity was taken as Fowler's solution, half an ounce of which it represents. Therefore arsenic should never be taken unless the dose and the manner of taking it is regulated by proper medical advice.

Arsenic should never be taken on an empty stomach, as it is very apt to produce irritating effects upon the stomach and bowels. It should, therefore, be taken only immediately after meals.

Arsenic should be taken only in very small doses to begin with. An ordinary dose of 5

drops of Fowler's solution given three times daily will produce, in many people, signs of irritation of the stomach, squeamishness, white silvery tongue, &c., whereas if a dose of 2 drops be given as frequently for several days, then 3 drops for a day or two more, and thus gradually the dose increased till the desired amount is reached daily, 12 to 30 drops, a tolerance will be established, and no signs of irritation produced.

When arsenic has been taken for a considerable period its use should not be suddenly stopped. A person who has been taking arsenic, in full doses, for a lengthened period, is likely when the need for it has disappeared to stop it all at once, as in the case of most drugs. This is a mistake. The sudden complete stoppage is apt to be followed, within even a few hours, by sickness, vomiting, headache, &c. Its use should be gradually stopped, even as it was gradually begun.

Arsenical Poisoning.—The symptoms of poisonous effects of arsenic are stomach pain, want of appetite, sickness, vomiting, diarrhœa, headache, silvery-white tongue, irritation of the eyes, and redness and swelling of the eyelids. If these symptoms arise in the course of using the medicine, the dose should be lessened; this is preferable to stopping the drug all at once. These symptoms are common in cases of chronic poisoning from the inhalation of vapour or dust containing arsenic. This used to be quite frequent, from the use of arsenic in the manufacture of wall-papers, to secure a brilliant green, and also from the wearing of articles of clothing, dyed with colours containing arsenic (see p. 732). This subject is considered at greater length in the next part, in the section devoted to poisoning.

Action and Uses of Arsenic.—Arsenic has a local effect upon the skin, used in the form of arsenious acid, which is for this purpose made up into a paste. It is employed to destroy growths. Its irritant action, when very mild, is occasionally made use of for stimulating the stomach. For this purpose very small doses are used, with the effect of aiding the appetite in certain kinds of indigestion. It is not, however, much employed for this purpose. Arsenic enters the blood and combines with the blood-corpuscles. It is sometimes used alone, or combined with iron, for bloodlessness—anæmia. It also is taken up from the blood by all the tissues and organs, remains in them for a short time, and is then cast off, being thrown off from the body by the urine, and to a slight extent also by the bile and skin. During its sojourn in the tissues it influences their chemical changes, the effect, when the dose is not excessive, being of a tonic and invigorating character. The arsenic-eaters of Styria, who begin with small doses, and are at length able to swallow 5 grains of arsenious acid at a time, do not suffer apparently, once they become habituated to the use of the drug, but present the appearance of strong healthy persons, and live to an old age. They have improved colour, increased muscular energy, and are able to climb the Styrian mountains without the breathlessness common to other people. *Some, however, die in the attempt to acquire the habit.* But the effects noted are due to the influence of the drug on tissue change. Arsenic is used in certain cases of bloodlessness, combined frequently with iron. Thus Blaud's pill (see p. 817) with $\frac{1}{60}$th grain of arsenious acid may be obtained of druggists, or the Fowler's solution with dialysed iron may be employed. Arsenic ranks next to quinine for its value in ague and malarial affections, and in affections exhibiting well-marked periods of recurrence, such as recurrent headache, periodic neuralgia, &c., it is very valuable. It is, therefore, said to be an anti-periodic. It is also used in nervous diseases, such as St. Vitus' dance and epilepsy. Its greatest employment, however, is in diseases of the skin, specially chronic diseases of the skin, such as eczema (p. 318), psoriasis (p. 319), &c. It has a special action on the skin, influencing the nutritive processes going on in a marked way. Very often it is combined with iron for this purpose, Fowler's solution, for example, with the compound iron mixture (p. 817). For skin diseases the solution of Donovan is also employed, combining the action of arsenic, iodine, and mercury, a combination much employed in skin affections dependent on syphilis. Finally, in chronic forms of lung disease, and in the early stages of consumption, its value is admitted, probably because of an improved condition of nutrition brought about in the lining membrane of the air-cells and fine tubes of the lung.

Mercury (Quicksilver) is a drug employed in a variety of forms and for very many purposes. Although we are considering it here for its influence on tissues, and its effect in bringing about an improved condition of general nutrition, still it will be well to note all its various actions and uses, to avoid considering it partly in one section and partly in another, though its effects on the bowel and liver, when given as blue pill, or as the cooling or "teething powder,"

with which probably everybody is familiar, will be further noted in the section devoted to drugs that act on the digestive system (section III.).

The chief preparations of mercury are as follows:—

	DOSE.
Calomel (Subchloride of Mercury)	$\frac{1}{2}$ to 5 grains.
Plummer's Pill (Compound Calomel Pill)	2 ,, 5 ,,
Gray Powder (Mercury and Chalk)	3 ,, 8 ,,
Blue-pill	3 ,, 8 ,,
(The size of pill usually sold by druggists contains 5 grains.)	
Blue Ointment (Mercurial Ointment).	
Corrosive Sublimate (Perchloride of Mercury: very Poisonous)	$\frac{1}{32}$th to $\frac{1}{16}$th grain.
Donovan's Solution (see p. 822).	
Red Precipitate Ointment (Ointment of Red Oxide of Mercury).	
Citrin Ointment (Ointment of Nitrate of Mercury).	
Black Wash (Lotion of Mercury). Made by adding 30 grains of Calomel to $\frac{1}{2}$ pint lime-water.	

Action and Uses.—Mercury is largely used as an application in the form of ointment or lotion to the skin. In the form of blue ointment it is used to destroy vermin. A solution of the corrosive sublimate is one of the most destructive agents of minute organisms, which are the cause of putrefactions and fermentations of various kinds, and is largely used in medicine and surgery as an antiseptic. Yellow precipitate and red precipitate ointment are common applications to chronic inflammatory states of the eyelids, as stimulant remedies. Lotions containing mercury are employed for the same stimulating effect, and as washes for ulcers, and sores slow to heal; calomel as a dusting-powder is used for the same effects. But ointments of mercury are very frequently rubbed on the skin, not for any effect to be produced on the part, but because they are absorbed from the skin into the blood and thus carried into the system. This method of administering the drug is called inunction. The usual course is to take a piece of blue ointment the size of a small bean and rub it well into the skin, in a situation where the skin is soft, such as the arm-pit or groin. This is continued daily till the effects of the drug manifest themselves. It is a method very applicable to children. A flannel bandage is put on the child, provided at one place with a small square pad, made of two or three folds of flannel, and sewed on the front part of the bandage. A small piece of ointment is smeared on this pad, and then the bandage is applied, the surface smeared with the ointment being next the skin. The bandage is fixed moderately tightly, and with the movement of the child the ointment is rubbed into the skin. Some newer preparations of mercury—the oleate of mercury ointment, for example—are more effective and active on the system than the old blue ointment, because they are more readily introduced through the skin. The usual method of administering mercury is by the mouth in the form of calomel, gray powder, blue-pill, solution of corrosive sublimate, or some of the more complex compounds of mercury, such as Donovan's solution, or the red or green iodides of mercury, compounds of iodine and mercury not named in the list given above. These substances are given by the mouth for one of two purposes: either to produce a purgative action and to influence the liver, or to be introduced into the system and to act upon the tissues generally. According to the effect desired is the form of drug prescribed, for, if a purgative action is produced, the most of the drug passes off in the motions and little enters the system. For the purgative effect calomel, gray powder, and blue-pill are commonly used. In the last two mercury is present in a metallic state, in a state of very fine subdivision. They appear to produce a purgative action by their local effect upon the stomach and bowels. They irritate the upper part of the small bowel, where the bile-duct from the liver enters (see p. 142), and thus cause the bile to be poured out of the liver into the bowel, although it would appear that mercurial preparations do not actually cause the liver to prepare more bile from the blood than it would otherwise do. They cause the liver, however, to deliver up its bile, so to speak, and then it is rapidly passed down the bowel by the quickened action of the bowel and expelled before much of it can be reabsorbed into the blood. A saline purgative, say a seidlitz-powder, given a few hours after a blue-pill, will thus aid its action by producing a flow of watery material into the bowel to wash it out more effectually. This is the reason for a blue-pill at night being followed by a seidlitz-powder in the morning. Gray powder is the form in which mercury is administered to children, for looseness of bowels, accompanied by the passing of greenish or curdy motions. While in many cases it is the appropriate remedy, it is given far too frequently and far too indiscriminately.

When the effect of mercury upon the system is desired, either some means is taken to prevent the purgative action of the calomel or blue-pill, or other preparations of mercury with less of a purgative action are employed, and especially the solution of perchloride of mercury (corrosive sublimate).

The action of mercury on the system is pro-

found, though obscure. It is taken up from the blood by every organ of the body, and specially by the liver, and it may remain in them for an indefinite period, so as to be detected in them after death. During its residence it influences in some unknown way the minute nutritive changes going on. It is removed from the body in the urine, bile, sweat, and is found in the saliva from the mouth and in the milk. Its most marked effects are shown as the result of the alterative action on the tissues. Thus organs which are the seat of inflammatory deposits or overgrowths are very often rid of the abnormal state of things by a prolonged use of mercurial treatment. In no disease is this so marked as in those dependent upon the syphilitic poison, attended by the multiplication of small cells among the tissues, specially of the nervous system and skin, little tumours being in time formed which by pressure on nerves, &c., produce paralysis and the multitudinous kinds of symptoms seen in this disease. The action of mercury, when appropriately and timeously given, is to dissipate these growths and effect a cure. It is also employed to aid the absorption of inflammatory thickenings, not necessarily syphilitic, as for example such as result in the cavity of the belly from peritonitis (see p. 190).

Precautions in the Use of Mercury.—When mercury is given in excessive doses injurious effects speedily show themselves. The first part of the body to suffer is usually the mouth. The gums become tender, red, and swollen; an unpleasant metallic taste is felt in the mouth, which is also hot. The breath is foul, the tongue thickly coated, and the appetite gone. The flow of saliva is increased and the glands at the side of the face enlarge and are painful. If the use of the drug is continued, ulcers form in the mouth, the tongue becomes swollen so that the person cannot speak, the teeth become loose, and chewing becomes impossible. There are also chilliness, a feeling of general depression, and perhaps vomiting, purging, and bloody stools. **Mercurialism** is the term applied to these effects; and the action on the salivary glands, resulting in swelling and the constant dribble of saliva from the mouth, is called **mercurial ptyalism.** In very bad cases death of part of the jawbone may occur. When persons are exposed to the action of mercury in small doses for a long time, another kind of effect may be produced, a condition of general enfeeblement, thinness, pallor, dyspepsia, muscular tremors and rheumatic pains, tendency to fainting, and palpitation, and impairment of sight and hearing may occur. This kind of symptom has been found in those exposed to the fumes of mercury in certain manufactures. Many persons are more liable to the influence of mercury than others. Even a single grain of calomel has been known to produce in an adult all the marked symptoms connected with the mouth. Persons cannot, therefore, be too careful in dosing themselves with mercurials, and it is very curious how often one meets with persons who have pronounced objections to be treated with what is vaguely called "metallic remedies," with whom the use of blue-pill at regular intervals is yet almost a passion, and whose children are dosed, on the smallest excuse, with "cooling powders" or the like. These persons are very much astonished to learn that blue-pill and gray powder are formed of metallic mercury very finely divided up. The marked effects of a debilitating kind shown on excessive use of the drug, or in persons very susceptible to its action, exist to a modified degree even when the dose is not excessive, and must be met by the administration of good food and by strict attention to the conditions of health, fresh air, &c.

Iodine is obtained chiefly from kelp, the ashes of sea-weed, and it is present in sea-water.

Its preparations are as follows:—

Liniment of Iodine.
Liquor of Iodine.
Tincture of Iodine.
} These are used for external application.

Iodine Ointment.
Iodide of Potassium................Dose, 2 to 10 grains.
Syrup Iodide of Iron............... ,, 20 to 60 drops.
(60 drops contain 4½ grains Iodide of Iron.)

Actions and Uses.—Iodine is used externally for its powerful irritant action on the skin and mucous membranes, being applied for its stimulating property and also for a disinfectant property to foul and discharging sores. It is also applied to the healthy skin for the purpose of acting on it much as a blister does, and so to bring the blood to the surface and relieve deeper parts. Thus it is often painted over the skin of inflamed joints after the acute inflammation has passed, for the removal of thickening, &c., in the joint, and on the chest following pleurisy and inflammation of the lung, to promote absorption of fluid or inflammatory products. It is used on the skin over enlarged glands, *when there is no active inflammation going on in the gland.* In the case of joints and chest affections, blisters are, in the author's opinion, much more useful, and in the latter case better results are obtained, without staining and injury of the skin, by the internal use of iodide of potassium or

syrup iodide of iron. The preparations used for external application are the liniment, the liquor tincture and ointment. The liquid preparations are most commonly diluted with glycerine. It is injected in the form of tincture into the sac of a hydrocele to prevent reaccumulation of fluid, and for a similar purpose in spina bifida (p. 457). When administered internally, the preparation of iodine enters the blood and passes to all the organs of the body. It is expelled from the body with great rapidity, specially in the urine, but it also appears in the secretion from the nostrils, in the sweat, in the saliva and in milk, and it may irritate the organs chiefly concerned in separating it, specially the nostrils, salivary glands, and skin. When the irritation is marked symptoms, classed together under the term **iodism**, are produced. The chief of these are running at the eyes and at the nose, pain in the forehead, and sensations connected with the nose and forehead resembling those of a common cold. There are also tenderness of the gums and mouth, increased flow of saliva, a feeling of rawness in the chest, and perhaps loss of appetite and sickness, and there is increase of mucus from the air-passages. A skin eruption occurs with some persons. While iodine is found in all the tissues of the body, it is found particularly in lymphatic glands, and secreting organs, salivary glands for example. Its most common employment is because of the effect it produces on these organs after prolonged use. In the case of thickening and enlargement of the glands, it produces absorption of thickenings; and, after a long time, it may even cause a wasting (atrophy) of the glands themselves. Indeed the quickening effect it induces on tissue change is taken advantage of to promote the absorption of effusions of fluid and inflammatory thickenings in any part of the body, but specially in connection with joints, and the cavities of the body. Thus it is frequently employed to aid the removal of the fluid in pleurisy, and other dropsies, and the inflammatory products in inflammation of the brain, water-in-the-head, &c. In scrofulous affections of glands, and scrofulous thickenings in general, it is invaluable, the best form for children being the syrup iodide of iron. In the later manifestations of syphilis, particularly its nervous manifestations, it is largely resorted to. The intense and continuous headache and the night pains of syphilis yield in a surprising manner to iodide of potassium, which is, in this instance given in large doses, 30, 60, and even 90 grains daily, if it can be borne, for it is a remarkable circumstance that large doses, 10 grains and upwards, are borne more readily than small ones, 2 to 5 grains.

Iodine forms easily-dissolved combinations with lead and mercury, and therefore it is administered in cases of chronic lead and mercury poisoning, for the sake of combining in the tissues with these metals and so securing their removal from the body. It is used in chronic rheumatism, and in large doses in aneurism.

Care should be taken that anyone being treated with iodide of potassium or iodine in other forms has abundance of easily-digested and nourishing food.

Phosphorus is obtained from bone-ash, in which it exists combined with lime.

Its principal preparation is:

Phosphorus Pill..........Dose, 1 to 3 grains, containing $\frac{1}{30}$ to $\frac{1}{10}$ grain of phosphorus.

Actions and Use.—Phosphorus has a marked effect on tissue change. In very small doses, given for a long time, it has been shown to act upon bones, increasing the amount of dense bone formed. In larger doses it leads to fatty degeneration of tissues, and, in cases of poisoning by phosphorus, extensive fatty change of liver, muscles, heart, and other organs is found. This is due to albuminous substances being broken down into a nitrogenous and a fatty portion, and the fatty portion being prevented uniting with oxygen. Phosphorus is administered in cases of nervous disease, nervous debility, neuralgia, paralysis, sleeplessness, being given as pill, or in combination with other drugs, such as zinc, with which it forms phosphide of zinc, of which the dose is $\frac{1}{8}$th to $\frac{1}{3}$d grain in pill. Then it is a common ingredient in the various compound syrups, used for general debility, lung diseases, and so on, in the form of phosphate of lime, or hypophosphite of lime, soda, &c.

Sulphur.—The principal preparations of sulphur are:—

Flowers of Sulphur (Sublimed Sulphur)..............................Dose, 20 to 60 grains.
Confection of Sulphur, or Sulphur Electuary: Flowers of Sulphur, 4 oz.; Cream of Tartar, 1 oz.; Syrup of Orange Peel, 4 oz. This is the same as the time-honoured "sulphur and treacle," treacle or ordinary molasses syrup being used instead of syrup of orange peel.....Dose, 1 to 2 tea-spoonfuls.
Sulphur Ointment (Flowers of Sulphur, 1 oz.; lard, 4 oz.).
Chrisma Sulphur.
Milk of Sulphur (Precipitated Sulphur)..............................Dose, 20 to 60 grains.

Action and Use.—Sulphur is used as a local application in the form of ointment for skin

diseases, and in particular for such as depend on parasites, such as itch. It appears that it is not the sulphur, as such, which is of value, but, in contact with the skin, compounds of sulphur are formed, namely sulphurous acid and sulphuretted hydrogen, which are destructive to the life of minute organisms. Sulphurous acid is liberated, as a gas, when sulphur is burned, and is liberated thus for purposes of disinfection; and sulphuretted hydrogen is also a gas, of nauseous foul smell. The smell of rotten eggs is due to the presence of sulphuretted hydrogen, produced from the decomposition of the albumin of the egg, for albumin contains sulphur in combination. Sulphurous acid in solution has been employed as a paint or spray for the throat in diphtheria, in the hope of destroying the fungus of the diphtheritic membrane, and sometimes with apparent success.

When sulphur is taken internally it stimulates the bowel and produces, without pain, an easy soft stool. It is, therefore, used as a laxative whenever there are conditions of the bowel, or neighbouring organs, in which more active purgatives would do harm, in cases of piles, for example, and pregnancy, &c. For this purpose the sulphur electuary is most valuable. Sulphur waters, such as those of Moffat and Strathpeffer in Scotland, Harrogate in England, Aix-la-Chapelle, Aix-les-Bains, Eaux-Bonnes, and others abroad, are used for similar purposes, as well as for other effects to be noted. These waters contain sulphur in the form of sulphuretted hydrogen or as salts, like sulphide of potash, &c. Sulphur when taken internally enters the blood as sulphuretted hydrogen, or salts, and is expelled from the body in the urine, and also by the breath and sweat. The breath may have the disagreeable smell of sulphuretted hydrogen on that account, and any silver articles worn about the person, silver coins carried in the pocket, &c., will be blackened by the sulphur excreted by the skin. In large quantities the sulphur compounds named act upon the nervous system in a depressing way, and it is perhaps owing to this that sulphur waters produce headache and depression on some persons. Having entered the blood the compounds reach the tissues, and modify their action in some unknown way. Because of this action, they have gained a repute in chronic rheumatism, gout, syphilis, and skin disease; while because of the laxative effect of sulphur waters, they are largely resorted to by those suffering from constipation and liver disorders.

Within recent years, Dr. Bergeon, of Lyons, has advocated the treatment of consumption and other lung diseases by injecting into the bowel carbonic acid gas, charged with sulphuretted hydrogen. A special apparatus has been designed for the purpose. It consists of a wide glass bottle in which a solution of soda is placed. To this is added tartaric acid. Carbonic acid is produced in large quantity, and is carried by a tube, guarded by a valve, to an india-rubber bag. From this bag a tube leads to a bottle containing a sulphur water, such as Eaux-Bonnes, or a solution of a sulphide from which sulphuretted hydrogen is liberated by the addition of a little of a solution of tartaric acid. The tube from the bag pierces the cork and dips down below the surface of the solution. The cork is pierced by another tube, which terminates, however, just inside the bottle, and this tube communicates with an elastic bag, similar to that of an enema syringe. From the other end of this elastic bag a tube passes off, the end of which is of a kind fitted for passing up into the bowel. When the elastic bag is squeezed any gas it contains is forced into the bowel, and when the pressure is relaxed carbonic acid gas is drawn into it from the india-rubber reservoir, bubbling through the solution of sulphuretted hydrogen on its way. The sulphuretted hydrogen is absorbed by the blood-vessels of the bowel, carried through the liver to the right side of the heart, and thence to the lungs, from the air-cells of which, according to Bergeon, it is expelled. His view is that as it thus passes through the lung tissue, it exerts an action upon the organisms of consumption destructive to their activity, a disinfectant action, and produces a healing influence on the diseased parts of the lung. The treatment has been highly praised abroad, and some good results have been said to follow its use by English physicians. It is only, however, in the early stages of the disease, and in slow chronic cases, that its beneficial effect is found, and it does not seem to retard at all the progress of acute cases, cases of galloping consumption. This latter fact the author has verified, as in a few cases of this kind in which he was able to have the method daily employed for many weeks, no benefit followed. The process of injection is somewhat tedious, half an hour to one hour being required each time; and it should be done certainly once, and, if possible, twice daily, about 2 pints of gas being injected each time. The bowel is thus filled with gas, and considerable discomfort is at first produced, aggravated by an almost unavoidable resistance on the part of the patient. After a

little experience, however, the discomfort is readily borne, resistance ceases, and the injection becomes very much easier. The process can be easily performed by a nurse, or anyone of average intelligence, after the method has been seen in action once or twice, so that after a day or two of practice the patient's friends can themselves carry out the treatment readily.

Sulphuretted hydrogen is a poisonous gas, and if inhaled in sufficient quantity will cause death by suffocation. Accidents of this kind have occurred to men entering cesspools for cleaning purposes, when they have been charged with the gas from decomposing materials. The breathing of air containing any quantity of the gas produces loss of appetite and headache in most people. In the use of the injection for consumption, therefore, the bottles should be kept well corked to prevent escape of the gas into the apartment, and if the gas is being expelled from the bowel, almost as soon as it is injected, one should proceed slowly till the bowel gets accustomed to the treatment, or stop altogether for a time. It is a remarkable fact that injurious effects from the gas are never produced on the patient, the explanation offered being that all the gas absorbed from the bowel passes into the venous system, and that the blood passing through the lung before it is distributed through the body is freed of the gas, which thus never reaches the tissues, and has no opportunity of exerting a poisonous effect.

Sarsaparilla is the dried root of a Jamaica plant.

Its preparations are:

	DOSE.
Decoction of Sarsaparilla	2 to 10 fluid ounces.
Compound Decoction of Sarsaparilla	2 ,, 10 ,, ,,

(Made of 2½ ounces Jamaica sarsaparilla, cut into pieces, sassafras in chips, guaiac wood turnings, and fresh liquorice root, bruised, of each ¼ ounce, mezereon, 60 grains, boiling distilled water, 30 ounces, evaporate to a pint.)

	DOSE.
Liquid Extract of Sarsaparilla	½ to 4 tea-spoonfuls.

Sarsaparilla had, of old, a high repute in the treatment of blood disorders, and especially in the treatment of syphilis, chronic diseases of the skin, gout, scrofula, and rheumatism. It is now practically neglected by most physicians, though as a domestic remedy it is still thought highly of. It appears to stimulate the skin and kidneys. It is given also along with iodide of potassium, and the beneficial effects it was believed to have on the system generally are supposed to be mainly due to such drugs combined with it.

Colchicum or Meadow Saffron yields several preparations, used in medicine, and derived either from the sliced corm or bulb, or from the fully ripe seeds.

Preparations:

	DOSE.
Extract of Colchicum (from the bulb)	1 to 3 grains.
Extract of Colchicum with Acetic Acid (from the bulb)	½ ,, 2 ,,
Wine of Colchicum (from the bulb)	10 ,, 30 drops.
Tincture of Colchicum (from the seeds)	10 ,, 30 ,,

Action and Use.—Colchicum increases the quantity of bile expelled from the body, and also causes an increase of perspiration. When the dose is too large it irritates the stomach and bowels, producing vomiting and purging, and great prostration. The heart is weakened, and breathing diminished, and the nervous system is depressed. Its main use is in gout, in acute attacks of which it is regarded as almost infallible, though it sometimes fails to afford relief. It markedly relieves the inflammation and pain, for which purpose ½ to 1 tea-spoonful of the wine may be given. It has been shown that while it does this, the effect produced is temporary, as the drug does not relieve the system of the cause of gout, the excess of uric acid in the blood and tissues, and, therefore, does not prevent a return of the attack. Thus the use of drugs such as lithia and potash which remove the uric acid are preferred, and "gout-ridden sufferers commonly advise their fellow-sufferers to abstain from colchicum." It is said to act best when administered with medicines, such as sulphate of magnesia (the ordinary "salts"), which produce a purgative action.

Guaiacum is used as a wood—*lignum vitæ*, and as a resin obtained from the tree stem.

From the resin the following are made:—

Guaiac Mixture..........Dose, 1 to 1½ fluid ounce.

(Made of powdered guaiacum, ½ ounce, sugar, ½ ounce, powdered gum arabic, ¼ ounce, cinnamon water, 1 pint.)

Ammoniated Tincture of Guaiacum..........Dose, ½ to 1 tea-spoonful.

Action and Use.—Guaiacum stimulates the lining membrane of the mouth, throat, and stomach, when taken internally, producing a feeling of heat in the mouth and stomach, and stimulating the movement of the bowel, causing purging, in large doses severe vomiting and purging. It also stimulates the heart by nervous influence. Entering the blood it excites the skin and kidneys, the liver, and tissue change in general. It is highly spoken of in the treatment of sore throat, quinsy, for which

it may be given in powder, 30 grains placed on the tongue and slowly swallowed, every six hours, or as the mixture, or in the form of lozenges, each of which contains 2 grains. In chronic rheumatism and gout it has been used with much success, the ammoniated tincture being advised.

Mezereum is the dried bark of *Daphne Mezereum*, or *Daphne Laureola*, the spurge laurel. In small doses it acts on the skin and kidneys, but in larger doses is a marked irritant, producing purging and vomiting. It is used in chronic rheumatism, scrofulous and skin disease, but is practically unknown in this country, except as an ingredient of the compound decoction of sarsaparilla (p. 828). As a liniment in combination with mustard and as an ointment it is employed externally.

SECTION II.—DRUGS WHICH ACT ON THE HEART AND BLOOD-VESSELS.

Drugs which Act on the Heart.

Heart Stimulants:
- *Ammonia*—Its Preparations and Use in Fainting;
- *Ether;*
- *Camphor;*
- *Alcohol*—How to Employ it as a Medicine.

Heart Tonics:
- *Digitalis*—Its Value in Weakness and Irregularity of the Heart;
- *Squills; Lily of the Valley* (Convallaria majalis);
- *Strophanthus hispidus.*

Heart Sedatives—Drugs which Soothe the Heart·
- *Aconite*—Cautions Requisite in its Use.

Drugs which Act on the Blood-vessels.

Drugs which Contract the Blood-vessels:
- *Ergot of Rye*—Its Use in Internal Bleeding;
- *Witch-Hazel* (Hamamelis virginica);
- *Acetate of Lead.*

Drugs which Relax the Blood-vessels:
- *Nitrite of Amyl*—Its Employment in Asthma.

Anyone who reads the 8th Section of the First Part of this work with understanding will appreciate the primary importance of a healthy condition of the blood, by which all the tissues and organs are maintained in a condition of activity, and will perceive the paramount necessity of the blood being distributed to the whole body with due regularity and in sufficient amount. It will matter little that the blood is of excellent quantity if it does not reach the tissues in a regular stream, nor will the body as a whole exhibit the evidences of a general well-being, if the blood lingers in overcharged vessels in one organ, while another is half-starved from a defective supply. The dependence of the body, therefore, upon the condition of the heart, which supplies the motive power for driving the blood through the body, and of the vessels, which are the channels of distribution, is fully evident. Speaking broadly, disorder of blood distribution will depend upon one of two circumstances: either the force-pump, the heart, is working improperly—too feebly or too strongly or irregularly; or, while the heart is working properly, the vessels are the cause of disturbance—contracted in calibre it may be, and thus opposing too great resistance to the onward flow of the blood, or relaxed and permitting too free a flow in one direction or another, tending to create some local congestion, or other disorder; or, of course, some element of disturbance may exist in both. The study of remedies which can be brought to bear upon the heart and blood-vessels will, therefore, be one of much interest. We shall, then, consider some of the chief drugs which act upon the heart and vessels, and the objects which may be gained by their use.

DRUGS WHICH ACT ON THE HEART.

Drugs which act on the heart may be roughly divided into those which stimulate the heart, which brace or tone the heart, **heart tonics**, and

stimulants, and drugs which quiet or soothe the heart, **heart sedatives, or heart depressants.**

Heart Stimulants and Tonics.

The heart is a muscular organ, the fibres of which are so arranged that, when they contract, the size of its cavities is diminished by a ringing or twisting movement, and the blood driven out into the vessels. If this movement be feeble, the heart will not be properly emptied with each contraction or beat, and the vessels will not be properly filled. The nutrition of the body will be imperfectly carried on. A good illustration of such a consequence, arising suddenly, is fainting or syncope. The heart is from some cause suddenly enfeebled, or its action almost arrested, and the brain being deprived of its needed supply immediately suspends its functions. If the cause be some momentary shock, the heart's beat is gradually restored, the circulation in the brain becomes re-established, and consciousness returns. Or if a stimulant be applied in some way to the heart so as rapidly to excite its activity, consciousness returns, and the colour returns to the face, pale from want of blood. Enfeebled action of the heart, whether brief, as in this case, or more long-continued because of some other condition, leads not only to failure of nutrition of the body, but also to defective nutrition of the heart itself. For the heart itself is supplied with blood by two arteries, the coronary arteries, which are the first branches to come off the main distributing vessel, the aorta (p. 223). So that if the heart is feebly propelling blood into the vessels, the heart is the first sufferer, and any long-continued feebleness will inevitably tend to perpetuate itself, because of the failure of the heart-substance to receive due nutrition.

Now the heart muscle may be stimulated directly, but is specially acted on, like other muscular organs, through the nervous system. Within the substance of the heart are nervous structures whose business it is to maintain the steady rhythmic movement of the heart. These may be acted upon and excited by remedies, administered and gaining access to the blood. These nerve ganglia, as they are called (for the meaning of ganglia see p. 85), are in turn controlled in their action by two nerves, the pneumogastric (p. 225), which restrains their action, so as to cause a slowing of the heart's beat, and, if excessive, a stoppage of the heart in a state of complete relaxation, and the sympathetic (p. 225), which excites them, and inceases the rapidity of the heart's action, leading, if excessive, to stoppage of the heart in a state of firm contraction. Acting, then, through one of these channels, stimulants increase the force and frequency of the heart's contractions.

Heat is one of the best and most rapidly acting of heart stimulants, whether in the form of a hot liquid taken into the stomach, or in the form of a hot sponge applied over the heart, or a hot-water bottle, similarly placed. It is exceedingly useful when it is necessary to act immediately, as in fainting or sudden collapse. It is drugs, however, we wish to consider specially, and the drugs which stimulate the heart are chiefly ammonia, ether, camphor, and alcohol.

Ammonia is a gas, used as a solution in water, from which it rapidly passes off. When one smells liquid ammonia, it is the gas coming off which produces the hot pungent sensation in the nostrils.

The chief preparations are:—

	DOSE.
Strong Liquor Ammonia	2 to 5 drops, well diluted.
The weaker solution to be preferred, if taken internally.	
Ammonia Water, or Liquor Ammonia	10 to 20 drops, well diluted.
Made with 1 oz. of the strong liquor to 2 ozs. of water.	
Sal Volatile, or Aromatic Spirit of Ammonia	½ to 1 tea-spoonful.
Liniment of Ammonia, Ammonia water, 1 oz.; olive oil, 3 ozs.	
Carbonate of Ammonia	3 to 10 grains.
Chloride of Ammonia	5 ,, 20 ,,
Solution Acetate of Ammonia (Mindererus' Spirit)	2 to 6 tea-spoonfuls.
Bromide of Ammonia (see Section on Drugs which Act on the Nervous System).	

Actions and Uses. — Ammonia acts as a stimulant to any surface to which it is applied. If applied to the skin it causes a hot burning sensation, and produces redness, and is, therefore, used as a liniment to rub over stiff joints, muscles, &c. If it is applied on a cloth and covered up, it will blister. But it is not usually employed for this purpose. It may be used to destroy the poison of snake bite, or to relieve the sting of insects and nettles—the weak solution. Raspail's sedative solution, used as a lotion for headache in women who suffer because of some womb derangement, is made with 2 ounces ammonia water, 2 ounces of common salt, 3 drachms camphorated spirit of wine, and 32 ounces of water. When applied to the nostrils as smelling-salts, or when the solution is sniffed (the weak solution should be used), the vapour of ammonia irritates the nostril, it excites the action of the heart, through the nerves, quickens

the pulse, and also quickens the breathing. It should not be used for too long a time for this purpose. A solution of any strength ought not to be held beyond an instant or so under the nostrils of an unconscious person, as the irritating vapour might inflame the nostrils and even the lining membrane of the lung tubes and lead to bronchitis. Taken into the stomach, it acts there also as a stimulant, but if used very strong or in too large quantities may occasion inflammatory action, and even cause death by its powerful effect arresting the breathing. Given in proper doses it not only stimulates the stomach, and produces a sensation of warmth, but it stimulates the action of the heart, even before any has time to be absorbed and act on the heart through the blood. The carbonate is the best preparation to give for this purpose. Its action on the stomach and bowel makes it useful for colic and flatulence. Carbonate of ammonia in 5-grain doses, with 5 to 10 drops of tincture of cayenne, and an ounce of infusion of calumba or other bitter infusion, is recommended to relieve the craving for spirits, and as a stimulant in cases, specially in women, when feelings of sinking and depression are felt. Carbonate of ammonia has also been used in scarlet fever, to diminish the fever and delirium, and has gained high repute, being given in 3 to 5 grain doses every two or three hours. Besides acting on the heart, ammonia acts as a stimulant to the bronchial tubes, increasing the action by which matters are swept up the tubes, and is, therefore, very valuable for aiding the expulsion of matter from the lungs, as in bronchitis when there is much expectoration. Its effect on the heart makes it specially useful in such cases. Given in the form of solution acetate of ammonia, it acts on the skin as a stimulant, promoting sweating; and this is a very simple and harmless preparation to give to children in feverish complaints, to promote sweating and diminish the heat of the body. Chloride of ammonium has been largely used in chronic cases of liver congestion.

Ether is discussed in the section devoted to drugs acting on the nervous system, along with chloroform. It may be used in cases of urgency to excite the heart or to dispel wind in the bowels in nervous and hysterical women. Of the ether itself, 20 to 60 drops are the dose given diluted or injected into the bowel, or the spirit of ether in 30 to 60 drop doses.

Camphor is a volatile oil, obtained from the wood of *Cinnamomum Camphora*, and imported from China and Japan.

	DOSE.
Camphor	1 to 10 grains.

Preparations :—

Camphor Water (Tie ½ ounce crushed Camphor in a muslin bag, and leave in 4 pints of water for at least 2 days.)	1 to 2 fluid ozs.
Camphor Liniment (1 oz. camphor, 4 ozs. olive-oil).	
Spirit of Camphor	10 to 30 drops (in milk or on sugar).
Paregoric Elixir, Compound Tincture of Camphor (Contains opium.)	15 to 60 drops (for adults).

Actions and Uses.—Camphor stimulates the skin, and is therefore used for liniments and ointments to relieve stiffness of muscles and joints, for sprains, &c. It stimulates the stomach, and is useful for dispelling wind, specially in hysterical subjects; but in large doses it irritates the stomach and causes sickness and vomiting, with a burning sensation at the pit of the stomach. The stimulating effect on the stomach and bowels renders it most valuable in cases of summer diarrhœa, attended by cramp. It is recommended in the form of spirit of camphor, 4 to 6 drops, on sugar or in milk, every ten minutes till the improvement occurs, and in 1 or 2 drop doses it is given to children in milk in like disorder of the bowels. At the very beginning of a cold in the head, the sniffing of camphor, or taking a dose by the mouth, very often relieves. For its stimulating action on the heart it is resorted to in fevers producing prostration. It strengthens the pulse and moistens the skin, checking delirium. It also stimulates the nervous system, but in excessive doses produces great excitement and convulsions, and if the dose be very large may cause death.

Alcohol.—The question of alcohol has been already discussed sufficiently (see p. 668). In the form of whisky or brandy it is usually most frequently at hand in cases of fainting. To relieve or ward off a fainting attack a small quantity, strong, is better than when it is much diluted, for the stimulating effect of the strong spirit on the mouth and stomach excites the heart even before any has had time to pass into the blood. In weak conditions, whether whisky is having a beneficial effect or not upon the heart can be determined by the state of the pulse, skin, tongue, breathing, &c. If the quick hurried pulse of fever is steadied, and slowed, while made stronger, if the breathing is quieter and more regular, if the skin is more cool and moist, and the tongue less dry and parched, and sleep is induced, the alcohol is having a good

effect. But if the pulse is more hurried, the patient more restless, the heat of the skin greater, it ought not to be continued. The effects it produces should be carefully watched for some time after a dose has been given to enable one to determine whether it should be continued or not. "Particular care should be taken in the administration of alcoholic stimulants to patients in the small hours of the morning. It is about this time that attendants are most apt to become sleepy, and therefore careless, and just at this time, also, the external temperature is lowest, the fire is apt to get low, and the vital powers of the patient are most likely to sink. In giving alcoholic stimulants to support the strength in disease, care must be taken that they are not given so frequently and in such large quantities as to disorder the stomach. Sometimes, when given very freely to support the failing circulation, they have this effect; the result of which is that both food and stimulants are vomited, and the patient may be brought to death's door." If whisky or brandy is found to be doing good the attendant is too apt to push its administration too far in the eagerness to secure the utmost advantage. This can only be avoided by a carefully accurate record being kept of the quantity used in 24 hours. It is not desirable to administer it in large quantities at long intervals, but in small quantities at short intervals. A very good way of accomplishing this is to give it in milk. Let a table-spoonful be mixed with a tumblerful of milk and kept covered, and let the patient receive sips of this every little while, every quarter or half hour, as may seem demanded. The quantity used in 24 hours is then counted as tumblerfuls of milk. A table-spoonful is $\frac{1}{2}$ oz. Now we have seen that, in health, 2 ounces of whisky or brandy is about the quantity that can be effectually disposed of in 24 hours, that would be 4 table-spoonfuls. But in disease very much larger quantities can be consumed without producing any sign of bad effects. Indeed children, even infants, can often take that quantity and above it, without being in the least affected by it. Larger quantities are, therefore, often demanded, specially in such cases as inflammation of the lungs accompanied by weak and failing action of the heart, bronchitis, and indeed in any diseases which imply a great strain upon the vital powers. It is remarkable how young children take this mixture of whisky and milk, and how often it seems to be the most beneficial thing to give in bronchitis with a great amount of material in the lungs, &c. For them the dessert-spoonful to each small teacupful of milk would be sufficient, and four or upwards of them might be used in 24 hours. Alcohol may often be replaced by such a stimulant as ammonia, but ammonia quickly passes through and escapes from the system, so that its action is short-lived, while the effect of spirits lasts for a considerably longer time, and can, therefore, be maintained more steadily and readily. Alcohol ought not to be employed in cases of nervous prostration, neuralgia, hysterical affections, sleeplessness. The risk of its use being continued, and continued to excess, and beyond the time of need, in all cases where the stimulant must be given for some time, or where the affection recurs at regular periods, is so great that it is better to seek some other means of producing the effect desired. In no class of cases is this more apt to occur than in women who suffer from nervous or hysterical attacks, or who are liable to regular periods of depression or pain at stated times. Every medical practitioner has met with cases where inveterate drunkenness has been traced to an illness when stimulants were given by medical orders, and when they were continued long after the order to give them was withdrawn.

Of **heart tonics** the chief are digitalis, squills, lily of the valley, and the most recent is strophanthus, the African kombé or arrow-poison.

Digitalis.—The leaves of digitalis, or the purple foxglove (see Plate XI.), are the parts of the plant used in medicine.

The preparations are:—

	DOSE.
Tincture Digitalis	5 to 30 drops.
Infusion of Digitalis	2 ,, 4 tea-spoonfuls (drachms).
Digitalin (the active principle)	$\frac{1}{60}$,, $\frac{1}{30}$ grain.

Action and Uses.—Digitalis acts upon the heart by increasing the force of its beat and lessening its frequency. Its effect is thus of a tonic character. At the same time it stimulates the nerves acting on the blood-vessels, diminishing their calibre. The heart is thus emptied at each beat more completely, the arteries are better filled, and are kept so by their diminished calibre, and the circulation is thus made more effective. The feeble heart is strengthened, and in cases where the beat is irregular, now fast now slow, now strong now weak, an occasional beat being missed and this being followed by a series of short, quick, feeble, fluttering, beats, its effect in appropriate doses is most marked and beneficial. The great disadvantage of digitalis is its tendency to derange the stomach and bowels, to produce loss of appetite, heartburn, vomiting, and sometimes diarrhœa, an

effect partly due to an irritating action on the lining membrane. This is one of the great difficulties in the use of the drug, for a patient cannot afford to have digestion deranged and disturbance of the first step in the nutrition of the body interfered with. In too large doses it produces irregularity of the heart's action, and poisonous doses cause death by stopping the heart. The drug has also a marked effect upon the kidneys, the result of which is greatly to increase the amount of urine passed.

The two purposes, then, for which digitalis is used are for affections of the heart, either when the heart is irregular in action from feebleness, when there is palpitation, or in certain cases of actual disease of the valves of the heart, and for cases of dropsy, because of its action on the kidneys. It is particularly serviceable in removing dropsical fluid by way of the kidneys, when the dropsy is due to bad circulation from some defect of the heart. It is useless to discuss here the kind of cases of heart disease in which it is useful, for in certain cases of heart disease, where the valves of the aorta (p. 239) are affected, it is held to be injurious. Whether it is likely to be useful or not is, therefore, a question for a skilled physician. It is in cases of weak irregular heart, unaccompanied by valve disease, specially in those well advanced in years, that its most marked effects are seen. One would begin with a small dose, 5 drops or so, thrice daily, and work slowly up, adding an extra drop or two daily till a steadying effect was produced, not going beyond 20 drops without great caution. In such cases sleeplessness is a very common symptom, and a marked degree of restlessness. This is due to the defective circulation, and often one of the first signs of marked improvement following the use of the drug is the passing off of the restlessness and sleeplessness, when the patient falls into a sound quiet sleep. The drug has a cumulative action, that is, it is not rapidly expelled from the body, and small doses continued for some time may suddenly lead to the production of unpleasant symptoms, sickness or faintness. In such cases the drug should be much diminished in dose. It must further be noticed that patients getting full doses of the drug should lie in bed; getting up on to their feet is apt to induce an attack of faintness.

Squills.—The squill is a pear-shaped bulb (*Urginea Scilla*) belonging to the lily order, and found growing along the shores of the Mediterranean. The bulb is sliced and dried for medicinal purposes.

Its preparations are:—

	DOSE.
Vinegar of Squill	15 to 40 drops.
Syrup of Squill (1 oz. vinegar of squill, 2 oz. sugar)	½ ,, 1 tea-spoonful.
Oxymel of Squill (5 oz. vinegar, 8 oz. honey)	½ ,, 1 ,,
Tincture of Squill	15 ,, 30 drops.
Compound Squill Pill	5 ,, 10 grains.

Actions and Use.—Squill acts upon the heart in a manner similar to digitalis. It is even more irritating to the stomach and bowels. Its common popular use is for cough, for which it is constantly given without judgment, in the form of syrup. It stimulates the lining membrane of the air-tubes, and increases the expulsion of phlegm and other matter. It is, therefore, useful in chronic bronchitis when the excretion is profuse, but not when active inflammation is going on. Its constant use, therefore, specially for children, ought not to be encouraged. It acts like digitalis upon the kidney, increasing the amount of urine.

Lily of the Valley (*Convallaria majalis*) resembles digitalis and squill in action on the heart and kidneys, and in its irritating effect upon the stomach and bowels.

Its preparations are the watery extract, of which the dose is 2 to 8 grains, and convallamarin, the active principle, of which the dose is ½ to 2 grains.

Strophanthus hispidus (*Kombé*) is one of the most recently introduced drugs, its employment being recommended, in certain cases of heart disease, by Professor Fraser, of Edinburgh, in 1887. The seeds are employed in Africa to yield an arrow-poison. Its chief preparation is:

Tincture of Strophanthus.......Dose, 2 to 5 drops.

Its action much resembles that of digitalis, being that of a tonic to the heart-muscle. It strengthens the beat of the heart and slows its frequency, the slowing action being sometimes very marked. It is used in certain cases of heart disease, but its action has not yet been sufficiently studied to enable one to say exactly under what circumstances it is useful. One advantage it seems to possess over digitalis is its less tendency to create sickness and irritation of the bowels, but in one case in which the author administered it in very large doses, severe cutting pains in the bowels occurred, apparently due to its action on the muscular wall of the bowel.

Heart Sedatives.

Drugs which soothe the heart, which diminish the force and frequency of its beat, are heart

sedatives. In one way they act by weakening the heart's action, by depressing it. Sometimes they are employed for such purposes, for example, in cases of severe inflammation or high fever in strong persons. But they are not, just on that account, remedies to be used except by those whose knowledge enables them to form a correct judgment of their suitability, and whose experience qualifies them to watch that their effects do not pass beyond the production of the desired result, for they can easily produce a dangerous weakening of the heart. It ought further to be observed that often an irritable, palpitating, heart, which the inexperienced would imagine needed soothing remedies, requires really tonic treatment. In some such cases the heart is irritable and irregular, and the patient feels it thump and bound unpleasantly against the chest wall, because it is weak, because it needs strengthening, and then anything which would depress it would act more injuriously, whereas anything which would exert a toning action upon it, such as digitalis, would speedily relieve the symptoms. What has been said ought to be sufficient by way of caution against the use of such drugs except under medical advice, and we shall consider only one of this class, but that one which is most frequently employed, namely, aconite.

Aconite.—The leaves, flowering tops and root of the *Aconitum Napellus*, or monkshood (see Plate XIII.), are employed in medicine, the two first to yield an extract, the last to yield a tincture, the preparation commonly employed.

Tincture of Aconite ....Dose, 5 to 15 drops.
Liniment of Aconite.

The active principle of aconite, aconitia, a most active poison, is employed for the preparation of an ointment.

Actions and Uses.—If aconite be applied to the skin it causes a tingling sensation, followed by numbness. If it be taken into the mouth and swallowed, a similar feeling is experienced in the tongue and gullet, and a sensation of warmth in the stomach, in large doses pain and sickness also. In large doses, after the drug has entered the blood and been distributed throughout the body, the same tingling is experienced in all parts of the body, the most sensitive parts being affected first, tongue and lips, then finger tips, face, breast, and the back last of all. This effect is due to the fact that the drug acts on the ends of the nerves of sensation, and reduces their sensibility. It is, therefore, used as a liniment or as an ointment for painful parts (Note: *where the skin is not broken*), such as in neuralgia, rheumatism, &c. The liniment may readily be used for such a purpose, never the ointment, unless ordered by a medical man, and it must be remembered that some of the drug may gain access to the circulation by the skin and produce its effects upon the body in general. When taken internally, besides the effects already spoken of, aconite specially acts upon the heart and upon the breathing. The heart is very quickly influenced, and usually by counting the pulse this can be noticed in a comparatively few minutes by the diminished pulse-rate. In excessive doses the heart becomes weak and irregular. The breathing is also slowed, made feeble and shallow, and in poisonous doses breathing is usually stopped before the heart ceases to beat. In excessive doses, also, great muscular prostration is experienced along with the tingling and numbness already mentioned, but the mental faculties are unaffected. In doses appropriate for remedial purposes the action is, then, to reduce the force and frequency of the pulse, to diminish the rate of breathing, and to lessen the sensibility of the skin, and also the skin becomes flushed and moist. It is, therefore, in acute inflammatory diseases, and in high fever, that its action would be beneficial. As a matter of fact it is mainly employed in such limited inflammations as quinsy, that is, inflammation of the tonsils and the throat, inflammation of the lungs (pneumonia) in strong and otherwise healthy persons, and in pleurisy. In such diseases its effect upon the heart very considerably abates the inflammatory symptoms, and in scarlet fever and other fevers, where the high degree of heat threatens mischief, it is also employed. In inflammation of the tonsils, inflammatory sore throat, where the pain and swelling of the throat are great, the fever high, the pulse very quick and bounding, and the face flushed, it commonly produces marked relief. As this disorder is not uncommon, and as the drug can be employed for it in a particular manner, which renders its use free from risk, it may be well to state how it should be employed, for the benefit of any who may be far from medical advice. The person should first make a note of the sufferer's pulse, noting number of beats per minute (see p. 11), regularity, &c. A single drop (*1 drop*) of tincture of aconite is then given in a little water, and this dose is repeated every quarter or half hour, according to the urgency of the case, the rate of pulse being noted before each dose, until a considerable slowing of the pulse is perceived,

DEADLY NIGHTSHADE or DWALE. (DEADLY DWALE.)
BLACK-CHERRY NIGHTSHADE.
(Atropa Belladonna)

FLY BLOWN MUSHROOM. FLY AMANITA.
(Agaricus Muscarius or Amanita Muscaria)

STRONG SCENTED or POISONOUS LETTUCE.
(Lactuca Virosa)

after which a drop every hour or every two hours may be sufficient to maintain the effect. Thus, suppose the pulse beating at first 120 times a minute or more, suppose a drop given every quarter of an hour, and in, let us say, three hours, the pulse-rate reduced to 100. Then the drug would be given at intervals of an hour, and if, in another hour, the pulse was still falling, say had fallen to 90, the dose would be stopped. If, after an hour or two, the pulse began to increase in frequency again, the drop every hour would be resumed, and if that did not control it, the drop every half-hour, to be again stopped when necessary.

From its effect on the sensory nerves, aconite is sometimes given internally in painful diseases like rheumatism, gout, lumbago, but is not to be recommended; and there are other drugs more certain to relieve, such as salicine, antipyrin, quinine, &c., which do not require so much caution in their use.

DRUGS WHICH ACT ON THE BLOOD-VESSELS.

The two actions which, for popular purposes, are all that it is desirable to consider under this head, are that by which blood-vessels may be caused to contract, so that less blood flows through them, and that by which they may be caused to dilate, so that more blood may flow through them. The former action one desires to secure locally, when a part of the body is in a state of active inflammation, and would be most readily secured by local cold, the application of cold-water cloths, of iced cloths, of evaporating lotions, and so on. It is the result one seeks also in order to control bleeding, and when the bleeding is external, cold, &c., is applied for that purpose (see under Accidents and Emergencies). On the other hand blood-vessels may be caused to dilate by the use of heat, hot poultices and fomentations, by the external use of mustard, which brings the blood to the skin by paralysing the walls of the vessels of the skin for a time, and so enabling the pressure of blood within them to widen them to their utmost limits. This action is performed when one desires to bring the blood to the skin and so to relieve deeper organs. Thus a mustard poultice over the chest brings the blood to the skin, and tends to relieve any deep-seated inflammation, and a mustard foot-bath is a very efficient way of bringing blood down from the head. There are several drugs, which taken into the system, act upon the blood-vessels in this way, causing their contraction and a diminished flow of blood through them, or causing their relaxation and a more easy flow.

Drugs which Contract the Blood-vessels.

Ergot of Rye is one of the **vascular astringents,** drugs which contract the blood-vessels. It is obtained from a fungus growing upon the common rye (see p. 565).

Its preparations are:—

	DOSE.
Liquid Extract of Ergot	15 to 30 drops.
Infusion of Ergot	1 ,, 2 fluid ounces.
Tincture of Ergot	15 ,, 60 drops.

Action and Use.—One of the chief actions of this drug is to cause contraction of the smaller arteries, and it is therefore in very common use to control internal bleeding, as from the lungs, womb, bladder, bowels, &c. It has also a special action upon the pregnant womb, which makes it a most valuable drug in bleeding after childbirth and other conditions. **Ergotism** is the term applied to a set of symptoms arising from poisonous doses, or protracted use, and has been seen frequently in certain parts of Germany where rye is the common article of food, and the diseased plant has been made use of. The symptoms are gangrene of the extremities, and nervous symptoms, such as a sensation as of insects crawling over the limbs, loss of sensation in hands and feet, flying pains, and convulsions.

Ergotin is a purified extract of ergot, given in pill form, the dose being 2 to 5 grains.

Ergotinin, the active principle of ergot, is employed to inject, under the skin, when one wishes to secure rapid action of the drug. The dose is $\frac{1}{300}$th grain.

Witch-hazel (*Hamamelis virginica*) or **Winter-bloom** is a shrub, 6 to 8 feet high, growing in damp woods and thickets in Canada and the United States of America. The flowers are collected in autumn. A liquid extract is prepared. In America a preparation known as **Pond's Extract** is derived from witch-hazel. It is clear, like water, and with a peculiar fragrance. A similar preparation is known in Britain as **Hazeline.** Of the two latter a tea-spoonful dose may be taken internally at intervals of 2 or 3 hours, and of a tincture, also prepared, the dose is 2 to 5 drops.

Uses.—Witch-hazel is used both internally and externally for bleeding. In bleeding from lungs, stomach, bowels, kidneys, and bladder any of the preparations named may be taken in the doses noted. For external bleeding, for cuts, and bruises it is applied as a lotion. For bleeding piles it may be used as a lotion, or a tea-

spoonful of the tincture in 3 ounces of cold water may be used as an injection. A dry extract is also prepared, which may be used as an ointment or made into a suppository. A tea-spoonful of the tincture, of Pond's extract, or of hazeline, mixed with a table-spoonful of warm water, is a useful lotion for inflamed eyelids, and to discharging sores it is also a valuable application.

Lead is largely employed to contract blood-vessels and control bleeding.

Its chief preparations are:

Acetate of Lead (Sugar of Lead)	Dose 1 to 4 grains in pill.	
Lead and Opium Pill	,, 3 to 5 grains.	
Solution of Sub-acetate of Lead (Goulard Extract)		used for external application.
Dilute Solution of Sub-acetate of Lead (Goulard Water)		used for external application.

Uses.—Lead is extensively employed as a wash for ulcers, sores, and inflamed surfaces, itching diseases of the skin, irritable piles, &c., relieving pain and itching and promoting healing. The highly inflamed and irritable sores are those suitable for this treatment, and the Goulard water is the preparation employed, diluted with several parts of water. The acetate of lead is a common ingredient in eye-washes, but ought not to be used without advice, as in some kinds of eye inflammation it is deposited as a white crust on the front of the eyeball. When given internally lead has a strong astringent action on the lining membrane of the stomach and bowels, and is used for bleeding from these surfaces and for diarrhœa and dysentery. The lead and opium pill is thus given, but ought not to be used without advice. Absorbed into the blood, it passes into distant organs and controls bleeding from the lungs, kidneys, and womb.

Lead-poisoning is frequent among painters, those engaged in colour-grinding, plumbing, type-founding, &c. The lead is derived from particles adhering to the hands and swallowed with food, from dust getting into the mouth, and inhaled from the clothes, &c. All workers among lead ought, therefore, to wash their hands and use a tooth-brush to the teeth before taking food, should not take food in the room where the work is going on, and ought to change their clothing as soon as work is over. A flannel respirator over the mouth and nose is, in some cases, needed, to prevent inhalation of the dust. Chronic lead-poisoning also arises from drinking waters contaminated with the metal. The symptoms of lead-poisoning are a blue line along the gums, colic in the bowel, usually accompanied by loss of appetite, cramps in the calves of the legs, and paralysis of certain muscles. Those of the wrist are chiefly affected, producing the characteristic "wrist drop," due to an inability to raise the wrist on the forearm. Headache and other brain symptoms also occur, disease of the kidneys also, and disease of the nerve of the eye, leading to dimness of vision and perhaps blindness. The treatment of lead-poisoning consists in removing the person from the source of the lead, and in giving some medicine which will aid in removing the lead from the body. For this purpose iodide of potassium is the drug used, in 5-grain doses, dissolved in water, given several times a day. Workers among lead are advised to take an occasional dose of Epsom-salts acidulated with a few drops of sulphuric acid as a preventative.

Drugs which Relax the Blood-vessels.

We all know that there are many means of relaxing the smaller blood-vessels of a part of the body and thus bringing a more copious supply of blood to the part. Thus putting the feet or hands in hot water brings the blood rapidly to the skin of these parts, and this can be effected elsewhere by the use of hot-water pads, hot poultices, and the like. Irritating substances, like mustard, have a similar effect. A mustard poultice reddens the skin by dilating the blood-vessels, and mustard, cayenne, camphor taken by the mouth, have a similar effect on the walls of the digestive canal. Such methods are often employed to withdraw blood from one part of the body threatened with or suffering from inflammation. Thus the purpose of applying a mustard poultice or a fly-blister to the walls of the chest in bronchitis or inflammation of the lung is to draw the blood from the deeper parts to the skin and so relieve the inflammation. The usual object of taking substances by the mouth which shall redden the walls of the stomach and bowels is to stimulate them to greater activity in the work of digestion, by bringing a more copious supply of blood for the production of the digestive fluids. Then there are many remedies which act upon special organs, exciting their blood supply and increasing their activity. For example, solution of acetate of ammonia relaxes the blood-vessels of the skin, and increases sweating. Alcohol has a pronounced effect of this kind. It dilates the surface blood-vessels all over the body, and thus induces a feeling of warmth. As a matter of fact, however, instead of causing an actual increase of heat to the body, it occasions a positive loss of heat, from the increased loss from

the surface (see p. 673). There are one or two drugs which very quickly dilate the blood-vessels all over the body; the chief of these is nitrite of amyl.

Nitrite of Amyl. This is prepared from amylic alcohol and nitric acid. It is an ethereal liquid of a yellowish colour, a pungent aromatic taste, and peculiar fruit-like odour. It was introduced as an anæsthetic by Dr. Richardson in 1863. When 2 or 3 drops are placed on a handkerchief and inhaled, after a momentary tickling sensation at the throat causing cough, the face begins to flush, the pulse becomes faster and fuller, and the breathing is much quickened. In about a minute the vessels of the head are felt to throb, there is a feeling of fulness in the head and a sensation of giddiness, especially if the person sits up. If a larger quantity be inhaled, the breathing becomes laboured, and the face becomes crimson, and later of a darker hue, and the sight becomes dimmed. These effects are due to the dilatation of the smaller arteries permitting a fuller and freer flow of blood to the surface, to quickening of the heart, and to an interference with the exchanges between the blood and the air. The drug is employed to dilate the smaller arteries in order to relieve spasm in angina pectoris (p. 243). The peculiar and intense pain of this disease seems to be due to some spasmodic condition of the smaller arteries, by which they become contracted in calibre, the pressure of blood within them consequently rising. It was because experiment had shown that nitrite of amyl had the power of producing an exactly contrary effect, dilating the small arteries and lowering the blood pressure, that it came to be tried in this disease. Results obtained from it have been just those which were anticipated, and it has become one of the chief drugs relied on to relieve the spasm. In some cases it has failed, and it has been suggested, that the failure may have been due to perfectly fresh nitrite not having been employed. It may be, that is to say, that the drug loses its power with keeping.

Pure asthma, nervous asthma, is also a spasmodic condition, in which the smaller bronchial tubes are greatly contracted. For this condition also nitrite of amyl is employed, and often with relief. It is for these purposes inhaled from a handkerchief in doses of from 2 to 5 drops, and the person should be lying down, lest faintness occur, and be attended by some one. It should not be given to full-blooded people, in whom there is any risk of apoplexy. It has been tried for epilepsy, sick headache (migraine), sea-sickness, but without much success.

Nitro-glycerine is employed in medicine in doses of from $\frac{1}{200}$ to $\frac{1}{50}$ grain, to produce effects similar to those due to nitrite of amyl.

Spirit of Nitro-glycerine, ... Dose, ½ to 10 drops.
(1 grain of nitro-glycerine in 100 drops of rectified spirit.)
Tablets of Nitro-glycerine, .. ,, 1 or 2 tablets.
(Tablets of chocolate weighing 2½ grains, and containing $\frac{1}{100}$ grain pure nitro-glycerine. Other strengths are also prepared.)

Nitro-glycerine acts like nitrite of amyl, and has been used for angina pectoris, epilepsy, neuralgia, spasmodic asthma, puerperal convulsions, neuralgia of stomach, and many other diseases. Its usefulness in many is dubious; in many persons the smallest dose produces intense headache; and in any case it is a drug of such power that a physician would use it only with great caution. In poisonous doses it produces great depression, the pulse and breathing become very much quickened, paralysis of motion and of sensation is produced; and if death results, it is by arrest of the breathing.

SECTION III.—DRUGS WHICH ACT ON THE STOMACH, BOWELS, LIVER, AND DIGESTIVE SYSTEM GENERALLY.

Drugs which Act on the Stomach.

Stimulants to the Stomach—Tonics:

Bitter Tonics—Angostura Bark, Calumba Root, Cascarilla Bark,
Chamomile Flowers, Chiretta, Gentian Root, Hops, Peruvian Bark, and Quinine,
Quassia Chips, Serpentary,
Their Preparations and Doses;
Acid Tonics—Dilute Hydrochloric, Nitric, and Sulphuric Acids;
The Uses of Acid Tonics;
Alkaline Tonics—Soda and Potash, Ammonia, Magnesia, and Lime;
The Uses of Alkaline Tonics.

Artificial Digestive Agents:

Pepsin—Its Preparation and Uses;
Pancreatin and Liquor Pancreaticus;
Papain—Its Ferment Action, and its Use in Diphtheria;
Ingluvin and Lactopeptin.

Remedies for Flatulence of Stomach:

Anise, Assafœtida, Camphor, Cayenne, Dill, Ginger, Peppermint, &c.

Emetics:

Warm Water, Mustard and Water, Infusion of Chamomile Flowers, and Carbonate of Ammonia as Emetics;
Sulphate and Acetate of Zinc, Copper, and Alum as Emetics;
Ipecacuanha—Its Preparations, Doses, and Uses;
Antimony (Tartar Emetic);
Apomorphia.

Remedies which Soothe the Stomach:

Ice as a Sedative to the Stomach;
Bismuth—Its Preparations and Uses;
Dilute Hydrocyanic Acid;
Belladonna, Opium, Oxalate of Cerium, Chloroform, Ether, Cocaine, &c., as Sedatives to the Stomach.

Drugs which Act on the Bowels and Liver.

Remedies for Constipation:

Laxatives—Fruits, &c.
Castor-oil; Senna and its Preparations;
Sulphur; Tamarind; Tamar Indien and Tamarind Whey;
Buckthorn, Dandelion (Taraxacum), *Glycerine, Olive-oil,* &c.
Simple Purgatives—
Rhubarb and Aloes;
Stronger Purgatives—Cathartics—
Colocynth, Gregory's Pill;
Scammony and Jalap.
Drastic Purgatives—
Elaterium, Croton-oil, and Gamboge.
Saline Purgatives—
Epsom-salts, Seidlitz-powders, Fruit-salts;
Cream of Tartar, Rochelle-salts, Glauber's-salts.
Purgatives which Increase the Flow of Bile—
Podophyllin; Euonymin; Iridin;
Hydrastin; Leptandrin; Juglandin;
Phytolaccin.

Remarks on the Use of Purgatives.

Remedies for Diarrhœa:

The Use of Opium, Castor-oil, Magnesia, Chalk, and Soda in Diarrhœa;
Tannic and Gallic Acids;
Catechu; Kino; and Rhatany;
Red Gum; Bael Fruit; Logwood; Oak and Elm Bark;
Alum, Iron, Copper, Zinc, and Silver Preparations.

Remarks on the Use of Remedies for Diarrhœa.

Remedies for Flatulence of the Bowel.

Remedies for Intestinal Worms: Anthelmintics:

Remedies for Tape-worm—Male-fern and Areca-nut;
Kamala and Kousso;
Pomegranate Root Bark and Turpentine.

Remedies for Round-worms—Santonica and Santonin;
Spigelia Root.

Remedies for Thread-worms—
Injections of Salt, Quassia, &c.

Injections for the Bowels: Enemata:

Nutritive and Stimulant Enemata;
Opening and Purgative Enemata—Salt, Soap, Castor-oil, Aloes, Turpentine, &c.;
Opium and Astringent Enemata—Enemata for Pain and Diarrhœa;
Enema for Piles.

Remedies which Act upon the Liver:

Stimulants to the Liver—
Nitro-hydrochloric Acid; Chloride of Ammonium.

Drugs which Depress the Liver—
Quinine, Opium, &c.

In this section we must consider the action of remedies upon several organs, stomach, small and large intestine, and liver, all of which are concerned in the digestive process. It is really impossible completely to limit the action of a medicine to one of these organs, and the effect which a medicine produces will most commonly be the combined result of its action upon several parts of the digestive canal. If, therefore, we consider the remedies which act upon the digestive apparatus under several subdivisions, such as those which act on the stomach, those which act on the bowel, those which act on the liver, and so on, it must be understood that the arrangement is mainly for convenience, and that the same remedy may be entitled to be included in each division.

DRUGS WHICH ACT ON THE STOMACH.

That the stomach may be acted upon in a variety of ways in order to influence the manner in which it performs its work in the digestion of the food will be plain to everyone who studies that part of Section IV. A. of Part I. which deals with the structure of the stomach (p. 138) and digestion in the stomach (p. 143). There it has been pointed out that digestion is carried on by the agency of the gastric juice, manufactured by the glands of the stomach from blood flowing in the vessels of the mucous membrane, aided by heat and the movements of the stomach walls. The quantity of gastric juice manufactured depends on the activity of the circulation, and it has been mentioned (p. 139) that the mere contact of the food with the wall of the stomach excites increased blood supply to the glands and increased flow of the digestive fluid. It has also been explained that the chief ingredients of the gastric juice are hydrochloric acid and pepsin, and that the whole process is under the influence of the nervous system. It is clear, then, that drugs may be given (1) which shall slightly irritate the mucous membrane of the stomach and determine a much larger flow of blood and, therefore, increased production of gastric juice; or (2) which shall also excite more marked movements of the muscular walls. But sometimes gastric juice in sufficient quantity may be produced but it is not sufficiently active, because of being deficient in acid or in pepsin, owing, it may be, to a state of general debility. In such a case (3) the deficient quantity of acid or pepsin may be made up by some being taken as a medicine. In all these cases the object is to stimulate the stomach, to rouse it to do its work better, more quickly, or more completely. These drugs will, therefore, be rightly called **stomach stimulants or tonics.** On the other hand, the lining membrane of the stomach may be unduly irritable, when the smallest quantity of food is apt to be rejected, as it often is in catarrhal states. Under these circumstances medicines which will soothe the stomach and diminish the irritability are desired, and these are called **stomach sedatives.** Another class of remedies are useful when, owing to some form of indigestion, the contents of the stomach become too acid, leading to heart-burn and acidity, or when the stomach is distended with wind and pained by the irregular spasm it induces. To the former remedies the term **antacids** is applied, and to the latter **carminatives** (from Latin *carmen*, a song, a charm), because they act quickly in relieving spasm as by a charm. Finally, there is a class of drugs employed to excite the stomach to eject its contents by vomiting—**emetics.** It is under these divisions that we shall consider the drugs which act on the stomach.

Stimulants to the Stomach: Tonics.

Bitter Tonics.

Bitter tonics are among the simplest of the drugs which stimulate digestion in the stomach. This they appear to do by stimulating an increased flow of gastric juice by their chemical action on the stomach walls, reddening the surface, bringing an increased supply of blood, exciting the nerves of the stomach, and thus improving the appetite and increasing the relish for food, as well as actually aiding the digestive process.

The chief bitter tonics are:

- Angostura or Cusparia.
- Calumba.
- Cascarilla.
- Chamomile.
- Chiretta.
- Gentian.
- Hops.
- Peruvian Bark and Quinine.
- Quassia.
- Serpentary.

The common form in which these substances are employed is that of infusion, and the usual dose is from 1 to 2 ounces.

It must not be forgotten that the action of these substances is stimulating, or to put it in other words, mildly irritating. If too much of the drug be used, or in too strong a form, the irritation may become excessive, and produce effects exactly the opposite of those desired, loss of appetite, diminished digestive power, and even sickness and vomiting. A very good example of this is afforded by the infusion of chamomile flowers, of which a dose of from 1 to 2 or even 3 ounces is a stomach stimulant, while 5 to 10 ounces act as an emetic. And here we have an illustration of the complex problem one often meets with in the treatment of disease—the indigestion of which one person complains may arise from an undue irritability of the mucous membrane of the stomach. If he seeks relief by the use of a bitter tonic, he will probably be surprised to find that, instead of aiding his digestion and improving his appetite, as he has been informed is its usual effect, the bitter has increased his disagreeable sensations. In short, the stomach already too irritable, is made still more so by the stimulating action of the medicine, and what he requires is a soothing remedy. One guide to the nature of the stomach condition is the appearance of the tongue, a very red tongue with prominent papillæ on its surface indicating an irritable stomach, while a flabby whitish tongue indicates the reverse.

Angostura or **Cusparia Bark** is the dried bark of a tree of tropical South America, the *Galipea Cusparia.* To make the infusion take 1 ounce of the bark in coarse powder, and add 20 ounces distilled water, heated to 120°; infuse two hours and then strain. It is used as a tonic in cases of weak digestion, and in recovery from acute diseases; and in warm climates it is found useful in intermittent fevers and dysentery. It may be noted that false angostura bark is the bark of the *Strychnos nux vomica,* which is poisonous, and the substitution of which for the pure bark has led to fatal accidents. The two may be distinguished from one another by the fact that the false bark when touched with nitric acid on the inner surface becomes blood-red, from the presence of a substance called brucia; the true bark does not.

Dose of infusion—1 to 2 ounces.

Calumba Root. The root of the *Jateorhiza Calumba,* or *Cocculus palmatus,* indigenous to the forests of Mozambique, and abundant along the lower Zambesi River. The infusion is made with 1 ounce coarsely-powdered root steeped for one hour in 20 ounces *cold* distilled water, and then strained. A tincture is also made which keeps, while the infusion does not.

Dose of infusion 1 to 2 ounces (2 to 4 table-spoonfuls).
,, tincture ½ to 2 tea-spoonfuls.

Cascarilla Bark, or sweet-wood bark, the bark of *Croton Eleuteria,* comes from the Bahamas. Of it also an infusion and a tincture are prepared, the former by pouring 10 ounces boiling distilled water over 1 ounce of the coarsely-powdered bark, and straining after an hour's infusion. The infusion does not keep well.

Dose of infusion 1 to 2 ounces, of tincture ½ to 1 tea-spoonful.

It is used not only as a tonic to the stomach, but also as an aid to the expulsion of phlegm from the air-passages in chronic bronchitis.

Chamomile Flowers are the dried flower-heads of the common chamomile, *Anthemis nobilis,* cultivated for the purpose. The infusion is made with ½ ounce of the flowers and 10 ounces of boiling water. It is strained after a quarter of an hour's infusion.

It is used as a tonic for indigestion with flatulence, and also for summer diarrhœa of children, and for sick headache; and is a useful lotion, when diluted with 1 or 2 table-spoonfuls of warm water, for inflamed eyelids. An oil may be distilled from the flowers.

Dose: 1 to 3 ounces as a tonic, 5 to 10 ounces as an emetic.

Chiretta is the entire plant of the *Ophelia Chirata*, collected in Northern India. The infusion is yielded by 1 ounce of the dried plant, cut small, and 40 ounces water heated to 120°, and is strained after half an hour. It is a pure bitter tonic, and has properties similar to gentian; its dose being the same.

Gentian Root is the dried root of the *Gentiana lutea*, found in mountainous districts of Central and Southern Europe, the Alps, Apennines, &c. From it are obtained a compound infusion and a compound tincture. The former is made with 1 ounce of the root, 1 ounce of bitter orange peel, 2 ounces of fresh lemon peel, and 80 ounces boiling water, infused one hour, and then strained. It is a very generally used tonic, a pure bitter, and also useful as a general tonic. An extract is employed in pill.

Dose: of infusion 1 to 2 ounces, of tincture ½ to 1 tea-spoonful.

Hops. The dried flower-spike of the female plant of the *Humulus Lupulus*, cultivated largely in England, is used to yield an infusion and a tincture, and also an extract. Of hops 1 ounce is used to 20 ounces of boiling water, and allowed to infuse for two hours; it is then strained. Hops contain a bitter principle—lupuline—and a volatile oil. They are used to impart the bitterness to beer. Besides being useful as a tonic to the stomach, hops have a soothing effect on the nervous system, tending to produce sleep. They are sometimes used in the form of a poultice or fomentation for painful swellings.

Dose: of infusion 1 to 2 ounces, of tincture ½ to 2 tea-spoonfuls.

Quassia Wood is the wood of *Picrœna excelsa*, growing in Jamaica. It is obtained in the form of chips and raspings. An infusion (60 grains of the chips infused for half an hour in 10 ounces distilled water and strained) and a tincture are its chief preparations. It contains a bitter principle, quassiin, but no tannin, and is therefore a simple bitter without astringence. Too large a dose is irritating to the stomach and causes vomiting. This wood is often made into a cup which imparts its bitterness to water allowed to remain in it for a short time. An infusion is used as an injection into the bowel to destroy thread-worms. The dose is the same as of gentian.

Serpentary—the underground stem of the *Aristolochia Serpentaria*, belonging to the southern part of North America. From it an infusion and tincture are prepared. The former is made with 1 ounce of bruised serpentary infused for two hours in 40 ounces of boiling water and strained. It is used in the production of compound tincture of cinchona (p. 820). It not only acts as a tonic to the stomach, but also stimulates the action of the kidney and skin, and is therefore employed in chronic rheumatism, and in low fevers.

Dose: of infusion 1 to 2 ounces, of tincture ½ to 1 tea-spoonful.

Peruvian Bark and Quinine have already been considered on p. 820.

Acid Tonics.

The acids chiefly used as stimulants to the stomach are:—

Dilute Hydrochloric Acid......	Dose	10	to	30	drops.
Dilute Nitric Acid	,,	10	,,	30	,,
Dilute Nitro-hydrochloric Acid	,,	5	,,	20	,,
Dilute Sulphuric Acid...........	,,	5	,,	30	,,
Dilute Phosphoric Acid.........	,,	20	,,	30	,,

The Uses of Acids. There is an obvious purpose in using acid to assist digestion. We have seen (p. 143) that the gastric juice is acid, that digestion in the stomach cannot occur unless the fluid be acid, and that the acid present is hydrochloric. It is easy to argue, therefore, that in cases of indigestion, the administration specially of hydrochloric acid will be a great aid, and in many cases this is so. For example, a person who, immediately after food, suffers from a feeling of weight in the stomach, which persists for a long time, and has hardly passed away before the next meal is due, or who after food is afflicted with a feeling of sickness, accompanied by the rising into the mouth of a quantity of a tasteless watery fluid (water-brash, see p. 181), perhaps ending in the vomiting up of a quantity of the unaltered food, will probably find much relief from taking 10 drops or so of hydrochloric acid in half a wine-glassful of water *after meals*. But this fact of the acidity of the natural stomach juice is not the only one which determines the employment of acids in stomach derangements. It is found that glands which produce an acid juice are excited to their work, or stimulated, by substances of an opposite character, that is by alkalies such as soda, potash, &c., and that their activity is diminished by the application of acid substances. On the other hand glands which produce an alkaline fluid are stimulated by acids, but have their activity lessened by soda or potash and such substances. Thus the fluid poured into the mouth from the salivary glands is alkaline, and

we know what a rush of fluid comes to the mouth when an acid substance is tasted, which is not experienced when some soda in water is taken. Thus a few drops of acid in water will promote the flow of the saliva into the mouth, but when it reaches the stomach will diminish the flow of the acid gastric juice. If acids are taken to assist digestion it must not be before food, for then they would only diminish the flow of gastric juice, but it ought to be after food, when the gastric juice has already been mixed with the food and one wishes to increase its acid properties. On the other hand if acidity and heartburn come on very soon after a meal, this implies that too much acid gastric juice is poured into the stomach. In such a case by taking acid *before a meal*, a person would hope to *lessen* the quantity of juice secreted, and so remedy the acid indigestion. But any one who is troubled with acidity and takes some drops of acid after food can expect only to increase his affliction. Exactly the reverse holds true with reference to alkalies, that is soda and potash. Soda or potash taken *immediately before a meal* excites by its antagonism a flow of the acid stomach juice, and is therefore a powerful remedy for indigestion due to deficiency of that digestive fluid. They should be taken *after a meal* only to correct acidity and heartburn, when they no longer encourage the flow of gastric juice, but neutralize some of the excess of acid. As a general rule, then, we may lay it down that to stimulate the stomach to the digestive process acid tonics should be taken *after meals*, and that a like purpose is served by taking alkaline (soda, potash) remedies *immediately before meals.* The best acid to use for this purpose is dilute hydrochloric acid. A similar explanation is offered for the value of acid drinks in relieving thirst, and moistening the mouth in fevers. They so stimulate the salivary glands and the glands of the mouth that a copious watery secretion results which moistens the mouth and throat. For this purpose a preparation of sulphuric acid, aromatic sulphuric acid, is very useful, a few drops in a glass of water. Citric acid, prepared from the juice of the lemon or lime, is also valuable, 17 grains in an ounce of water making a solution resembling lemon juice.

Besides the effects in the stomach that have been noted, acids produce a further action when they reach the small intestine, explained in a similar way. The bile is poured into the small bowel a few inches below the opening of the stomach, and the pancreatic juice in its neighbourhood. Both these juices are alkaline, and thus when the acid contents of the stomach pass over the openings of the channels from these organs, the result of the irritation is a copious flow of the two juices. Acids are thus frequently given for the avowed purpose of stimulating the liver, the dilute hydrochloric and dilute nitro-hydrochloric acids, in 10-drop doses, being specially used for this purpose. In chronic cases of sluggish liver they are very serviceable. They are also used as general tonics, phosphoric acid being employed in cases of nervous exhaustion.

It must not be forgotten that while the use of dilute acid in indigestion may afford great relief in appropriate cases, it must not be too long continued. Their employment for a prolonged period continuously defeats the end aimed at. Their beneficial effects become lessened because, by and by, they tend to induce catarrh of the stomach and bowels. The proper plan, therefore, is to employ them for a week or two, then to stop and substitute an alkaline tonic, taken before food (see below), for a week or two, and then, if need be, to return to them again for another brief period. This tendency with prolonged use to set up catarrh, and therefore interfere with digestion, is alleged as the reason for the effect of vinegar in reducing fatness, and this is not a purpose for which they ought to be used. The scientific method of reducing fat is fully explained on p. 625.

For many other conditions of the stomach and bowels, besides that of simple indigestion, are acids administered. Their constringing action on the lining membrane makes them useful in bleeding from the stomach or bowels and in diarrhœa, dilute sulphuric acid being the one specially used. Indeed sulphuric acid is employed for controlling bleeding in other organs, the lungs and womb, for example. To reach these organs it must pass into the blood, and it is not conveyed in the form of acid but in chemical combination as sulphates, and how it in this condition controls bleeding is unknown. It has also a marked effect in relieving profuse sweating. The organic acids, citric, tartaric, and acetic, chiefly the former, are employed in rheumatism, but they never reach the tissues in that shape, but in the form of citrates of potash, &c. &c., when they have lost their acid properties.

It will complete our view of the action of acids, and avoid the necessity of anything more than a mere reference in other sections, if we note here some of the local actions of acids. In their undiluted form they are powerful irritants, and some of them exert powerfully destructive

actions on the tissues. They are occasionally used for such purposes. Strong nitric acid is employed to destroy foul sores, and to restore a healthy action to certain ulcers. Applied immediately to a part bitten by some poisonous animal, it prevents the possibility of absorption of the poison into the system. Acetic acid and glacial acetic acid are applied to warts. Such applications must be made with the greatest care, the part being simply lightly touched with a glass rod dipped in the acid and immediately thereafter bathed with cold water, and special care must be taken to prevent the acid running on to the sound skin. Dilute acid is used with which to sponge the skin in fever, producing a grateful cooling effect, and is similarly used to limit excessive sweating. Very dilute solutions of acetic and sulphuric acids are the best for this purpose. A tea-spoonful of *dilute* nitric acid to a pint of water used as a lotion for swollen and bleeding piles affords marked relief.

Alkaline Tonics and Remedies for Acidity: Antacids (Soda, Potash, &c.).

The alkaline medicines used as tonics are:—

Compounds of soda,
,, ,, potash,
,, ,, ammonia,
,, ,, magnesia,
,, ,, lime.

Potash and soda have already been discussed on p. 818 and 819, the chief compounds employed being the bicarbonates of potash and soda and the solution of potash. We shall note a few of the preparations of ammonia, magnesia, and lime, and then consider the effects of alkaline tonics as a group, as we have done with acids.

Ammonia is, when pure, a colourless gas with a very pungent odour. The ordinary liquor ammonia, or hartshorn, is a solution of the gas in water. It was called hartshorn because it was readily obtained from animal substances, such as horn, hoof, &c. The chief compounds of ammonia are as follows:—

Strong Solution of Ammonia,
Ammonia Water (Hartshorn) ...Dose, { 10 to 20 drops well diluted.
1 ounce of the strong solution mixed with 2 ounces of water.
Aromatic Spirits of Ammonia. Dose, { ½ to 1 tea-spoonful in water.
Carbonate of Ammonia.......... ,, 3 to 10 grains.
Chloride of Ammonium.......... ,, 5 ,, 20 grains.
Solution of Acetate of Ammonia (see under Section on Drugs that act on the Skin).
Bromide of Ammonium (see under Section on Drugs that act on the Nervous System).

Uses.—Ammonia is used externally as a stimulant. Thus the vapour of hartshorn and of carbonate of ammonia in the form of smelling-salts is employed in fainting and to relieve headache, when sniffed up the nose. It must not be used too strong, as it might excite inflammation. Applied to the skin as hartshorn it reddens the part, and is, therefore, used for rheumatic joints and as a liniment for other affections. Similarly when ammonia is taken into the stomach, either as hartshorn diluted, or as carbonate of ammonia, or as the aromatic spirit, it stimulates, producing a feeling of warmth in the stomach; and it excites the stomach and bowels to the expulsion of wind. For such a purpose the aromatic spirits are best.

The chloride of ammonium has a special action on the liver, and is largely used in tropical countries for congestion and other chronic liver diseases. Entering the blood it acts as a general stimulant, rousing the heart and nervous system, and rallying the vital powers in states of exhaustion, exciting also the air-passages and the nerves connected with the lungs and aiding in the expulsion of mucus from the air-tubes in chronic bronchitis. For these latter purposes 5-grain doses of the carbonate are best. If 30 grains of this drug be given well diluted it acts as an emetic, and is occasionally used for this purpose in chronic bronchitis and croup, as the vomiting expels also the material from the air-passages. Ammonia is used in cases of snake bite, and for relief of stings of insects. For the latter weak solutions of hartshorn are applied to the part, and act by destroying the poison of the bite; for the former 10 drops of the strong liquor diluted with 30 of water are injected into the veins, and act by their stimulating property on the circulation and nervous system.

What is said a little further on as to the uses of alkaline medicines in indigestion is applicable to ammonia, the preparation chiefly used being the aromatic spirits. It is not commonly employed alone but along with soda or potash and with some bitter infusion.

Magnesia.—The chief preparations of magnesia are:—

	Dose.
Carbonate of Magnesia...........	10 to 60 grains.
Fluid Magnesia (Solution of Carbonate of Magnesia)...	1 to 2 fluid ounces (2 to 4 table-spoonfuls).
Light Magnesia.......................	10 to 60 grains.
Heavy Magnesia (Ponderous Magnesia).....................	10 ,, 60 ,,
Sulphate of Magnesia (Epsom Salt)...........................	60 grains to ½ ounce.

Uses.—Magnesia is chiefly given for correction of acidity of the stomach and heartburn and

for acidity of the bowels. The carbonate, light and heavy magnesia are not easily dissolved, and they are therefore specially useful for acidity. They also act upon the bowels so as to cause a copious flow of watery secretion, producing loose motions. As they have not much stimulating effect they cause no griping pains and are thus useful for children, for whom they are often combined with rhubarb, as in Gregory's powder. A useful combination would be 5 drops or more of the aromatic spirits of ammonia. The action of Epsom salt will be discussed under Purgatives, in this section.

Magnesia in powder is, however, given too freely, and is apt to form little stony concretions in the bowel if persistently used in any quantity. Magnesia is a common antidote for poisoning with strong acids, oxalic acid, mercury, arsenic, and copper, as it forms with them insoluble salts.

Lime or chalk.—Its chief preparations are:—

	Dose.
Prepared Chalk (Carbonate of Lime)	10 to 60 grains.
Lime-water (shake up slaked lime in water. Allow to stand, and pour off the clear fluid)	½ to 4 ounces (1 to 8 tablespoonfuls).
Saccharated Solution of Lime	15 to 60 drops.
Chalk Mixture	1 to 2 ounces.
Aromatic Chalk Powder	10 to 60 grains.
Grey Powder (Mercury with Chalk)	2 to 8 grains.
Phosphate of Lime	10 to 20 grains.
Hypophosphite of Lime	5 to 10 grains.

Uses.—Lime is, like magnesia, exceedingly useful as a corrective of acidity and heartburn when given after food. It has also an astringent property, for which it is much used in looseness of bowels, specially in the form of chalk mixture, or for children the aromatic powder. Lime-water is given freely to children being artificially reared, much too freely in the author's opinion. Over and over again he has asked mothers and nurses for what purpose the lime-water was added to the milk; and if he has received any answer, for commonly no reason except that of custom or the advice of somebody supposed to know has been forthcoming, the answer has been that it was to help in the formation of the child's bones. This idea is quite incorrect, most of the lime is expelled in the motions. The actual reason for the addition of the lime-water is that it destroys—neutralizes—some of the acid of the gastric juice, and therefore prevents the rapid action of the juice on the milk, in short slows the process of digestion in the stomach. It must be remembered that the first effect of the gastric juice is so to act upon the milk as to separate it into a curd and whey, and then the curd is further attacked and broken down. Now mother's milk forms, in the stomach of the child, a very fine curd, in small flaky pieces which are easily digested. Cow's milk, however, forms much larger and more solid masses, which are apt to irritate the child's stomach and cause vomiting, griping pains, colic, diarrhœa, &c. The addition of the lime-water, by diminishing the acidity of the gastric juice, slows the process, so that smaller pieces are formed. It is, therefore, quite a correct thing to do *if it is necessary*, if, that is, the child shows any difficulty in digesting the cow's milk when prepared in a proper way (see p. 441), and if simple boiling, which prevents the milk curdling in large masses, does not prove sufficient to remove the difficulty. But the use of lime-water *as a matter of course* and without any proof of its necessity in the milk prepared for every hand-fed infant, and in every bottle, is a thing to be most strongly objected to and prevented. When it is necessary about one tea-spoonful of lime-water, or 15 drops of the saccharated solution, may be added to the milk. For diarrhœa a similar quantity and upwards may be used. The phosphate and hypophosphite of lime are the preparations employed in growing children suffering from chronic diarrhœa and general weakness, but they are more advantageously given in combination with tonics, as in Parrish's Chemical Food, Syrup of the Hypophosphites, &c. (see p. 817).

Chalk is employed as a dusting powder for burns, ulcers, and weeping patches of skin eruptions, for its soothing and astringent effect. Lime-water is used for the same purpose; and Carron-oil, a mixture of lime-water and linseed-oil, is one of the most soothing of applications to burns. Lime-water is also employed as a mouth-wash in ulceration, and for injection into the bowel to destroy round-worms.

The Uses of Alkalies.—The conditions under which acid tonics are found to be useful in indigestion have been stated in detail on p. 842, and enable one to understand also under which circumstances medicines of an opposite chemical character should be employed. The stomach juice is acid, and its flow will, therefore, be stimulated by a remedy of an opposite kind, soda or potash. The appropriate time, therefore, for the administration of alkaline tonics is immediately before food, so that the food afterwards introduced into the stomach is met by an abundant secretion of juice for its digestion. In all cases of slow digestion, in which the food lies like a weight for hours after it has been taken,

and after an hour or two, it may be, causes great uneasiness by the development of flatulence owing to improper fermentations arising, in all such cases alkaline remedies before food should first be tried, in preference to acid remedies taken after food. They are not usually taken alone, but in combination with some other substances, which will aid their stimulating action on the stomach. For example, a few grains—3 to 5—of bicarbonate of soda or potash, along with half a tea-spoonful of aromatic spirits of ammonia, and a tea-spoonful of a bitter tonic, say infusion of calumba, or other bitter infusion (see p. 840), or ½ tea-spoonful of compound tincture of gentian, in a wine-glassful of water, would make such a combination as would be found suitable for many cases of weak and sluggish digestion, or **atonic dyspepsia,** as it is called. If such treatment did not yield complete relief, then, after a time, one would substitute an acid tonic, taken *after food*, say 5 to 10 drops of dilute hydrochloric acid, along with a bitter infusion also.

An entirely opposite effect to that which has been described is obtained by giving soda or potash *after* a meal. Then the alkali simply mixes with the acid contents of the stomach and neutralizes some of the acid, so that the total acidity is diminished; it has then no effect upon the secretion of gastric juice. It is in cases of acidity and heartburn that the soda and potash are useful in this way. Here also it is well to give them in combination with such a preparation as the aromatic spirits of ammonia, which will aid in the expulsion of any wind that has formed. It is to be noted, however, that this use of alkalies is able to give only temporary relief. It diminishes the acidity at the time, but does not remove the condition which has been the cause of the disturbance. Acids given *before food* will, on the principle already explained, *restrain* the secretion of the acid gastric juice, and may thus prevent the excessive acidity from occurring at all. We may then usefully summarize the results of the employment of acids and alkalies in indigestion by the following table:—

Acids given after food increase the acidity of the gastric juice, Alkalies given before food stimulate the secretion of the gastric juice, ...	and thus promote digestion.
Acids given before food restrain the secretion of the gastric juice, ... Alkalies given after food diminish the acidity of the gastric juice,	and thus relieve acidity and heartburn.

In certain forms of diarrhœa, dependent upon the irritation produced in the bowel by the excessive acidity of the bowel contents, soda, potash, magnesia, and lime, by neutralizing some of the acid, are most valuable. The benefit derived from such drugs in increasing the alkaline character of the blood has already been pointed out on p. 818.

The principle that an alkaline solution will increase an acid secretion, but will restrain an alkaline one, explains the effect of a solution of carbonate of soda in certain skin diseases, accompanied by raw surfaces, which weep copiously, such as eczema. The fluid from the eczema is alkaline, and is much relieved by bathing with 30 grains of the carbonate to a pint of water. The itching of nettle-rash and other skin affections is often wonderfully relieved by a similar lotion, or one double the strength.

Artificial Digestive Agents.

The ferment—pepsin—present in the gastric juice can be separated from the stomach of animals, such as the pig and the calf, and can be prepared in a pure state, and administered as a medicine to those whose indigestion seems to depend upon deficient quantity or quality of the gastric juice. In the same way the ferment of the pancreatic juice—pancreatin—can be prepared and employed as a medicine. Recently it has been found that the juice of the papaw-tree has digestive properties resembling those of pepsin, and from it a ferment—papain—has been separated, of which we shall give also a brief note.

Pepsin.—The ordinary pepsin is prepared in the following way:—The stomach of a recently killed pig, sheep, or calf is opened up and laid on a board, inner surface upwards. Adhering portions of food, dirt, &c., are washed off by a gentle stream of cold water. The surface is then scraped with a blunt knife or other suitable instrument, and the scrapings spread on a surface of glass or glazed earthenware, and quickly dried at a temperature not exceeding 100° Fahr. The powder thus obtained is yellowish-brown, with a peculiar odour, and should be kept in a dry stoppered bottle. A glycerine extract of pepsin is easily made by stripping the inner lining membrane—the mucous membrane—off the stomach of a recently killed pig or calf, cutting the stripping up into small pieces, and pounding them up with glycerine. Leave the mixture for eight days, and then press the fluid through cloth. The glycerine extract so obtained will show all the active properties of pepsin.

Pepsin	Dose 2 to 10 grains with food.
Saccharated Pepsin	,, 5 to 15 ,,
Liquor Pepticus	,, 1 tea-spoonful.
Acid Glycerine of Pepsin	,, 1 to 2 tea-spoonfuls in water.
Pepsin Wine	,, 1 to 2 tea-spoonfuls with food.

Uses.—If a glass beaker or tumbler be taken, a quarter full of water, and if into it be placed some pieces of lean meat, cut very small, small pieces of cooked egg, small pieces of fish, &c., and if there be added to the water a similar quantity of the solution of hydrochloric acid (4°/$_o$), and a pinch of pepsin, or a tea-spoonful of liquor pepticus, and the glass vessel be then set aside, and kept at a temperature of 100° Fahr., in three or four hours the contents will be partially digested, and the fluid will have acquired a pea-soup appearance and a peculiar odour. If a second tumbler be similarly prepared, and have the same contents, except the pepsin, the fragments of food will show only a swollen gelatinous appearance, no evident solution having occurred; or, if, again, a third tumbler be prepared, and pepsin be added, but no acid, little or no change will occur. In short, for purposes of digestion, both pepsin and acid must be present. If, therefore, one is administering pepsin as an aid to digestion, it is well to give it in an acid solution, in combination, that is, with hydrochloric acid. Now, 6 drops of hydrochloric acid in 1¼ ounce of water give a strength of hydrochloric acid about equal to ·4 per cent, and 6 drops in 2½ ounces of water, or the average sherry-glassful, are equal to ·2 per cent, the exact strength of the acid of the gastric juice, so that 2 to 5 grains of pepsin, 6 drops of dilute hydrochloric acid, and half to one wine-glassful of water would meet the requisite conditions. The cases in which pepsin is considered desirable are those of general debility and anæmia (bloodlessness), where, owing to the general weakness, a deficient supply of gastric juice is the cause of indigestion; and also cases of chronic catarrh of the stomach, such as the chronic dyspepsia of drunkards. It is also needed in cases of irritable stomach, when pain after food is a frequent symptom and subsequent vomiting; in cases of ulceration of the stomach, in which the desire is to relieve the stomach of its work as much as possible; and in the weak digestion of the old and of infants. Of course in the case of children much smaller doses would be employed.

A caution against the routine use of pepsin must be given. It must be noted that if the work of the stomach is done for it, there will be a tendency to lower the activity of the stomach, and if this is long and constantly persisted in, the stomach will become less and less able to do its business. It is, therefore, always desirable to use other remedies to correct indigestion, stimulating remedies with a view to stirring up the stomach to perform its duties, such as the acid or alkaline tonics already noted, combined with tonics to the nervous apparatus of the stomach, such as nux-vomica; and pepsin preparations ought to be employed only for a time to tide over some temporary difficulty. In short, pepsin should be of the nature of a last resort, and never a first.

Liquor pepticus is a solution of pepsin, and may be employed in such cases as pepsin itself. The liquors of Savory and Moore or of Benger are those most widely used.

In cases where it becomes absolutely necessary to relieve the stomach of some or the most of its work by partially digesting the food artificially, such as cases of ulceration of the stomach, and in the case of children, not being nursed by the mother, in whom the stomach rejects cow's milk, condensed milk, and all forms of prepared food, it is customary to effect the object by adding the digestive agent to the food sometime before it is administered, and thus accomplishing the partial digestion before it reaches the stomach at all. Pepsin is not commonly employed for this purpose, because it digests only one class of food-stuffs, namely proteids. The addition of pepsin and acid to milk, for example, would effect only the digestion of the curd of the milk (see p. 549 for composition of milk), and would leave unaffected the cream or fat of the milk. If it were added to a mixture of milk and arrow-root it would not act upon the arrow-root at all, pepsin not digesting starch (see p. 586). When digestion of food is to be accomplished before its administration, therefore, pancreatin or liquor pancreaticus (see below) is employed, since it acts not only on albuminous, but also on starch and fatty foods (see p. 145).

Pancreatin is derived from the sweet-bread or pancreas of the pig. It is a mixture of ferments, one of which is capable of digesting albuminous substances, a second starchy foods, and a third fatty materials. A glycerine extract of pancreas may be prepared by cutting up the fresh sweet-bread of the pig and pounding it up in glycerine, letting it remain so for eight days, and then straining it through cloth. In the market there are several very active solutions of the pancreatic ferments, the best known being the liquor pancreaticus of Savory and Moore

and the liquor pancreaticus of Benger. Zymine is a preparation in the form of a yellowish powder obtained from Burroughs, Welcome, & Co., London.

Preparations:

	Dose.
Pancreatin	2 to 4 grains.
Liquor Pancreaticus	1 to 2 tea-spoonfuls in water with a pinch of baking soda 2 or 3 hours after a meal.
Pancreatic Emulsion prepared with the pancreas of the pig and fat and flavoured	1 to 3 tea-spoonfuls in a little milk or water 2 or 3 hours after a meal.

Now a set of experiments with pancreatic solutions may be made in tumblers, such as have been described for pepsin. They show that pancreatin or liquor pancreaticus alone, added to a tumbler containing water and small pieces of food-stuffs, will scarcely act at all. Nor yet will any action whatever occur if acid be added to the solution. But if to the food and pancreatic extract in the tumbler be added a good pinch of bicarbonate of soda, in an hour or two the digestion of the food will be far advanced. That is to say, *while pepsin acts in an acid solution, pancreatic juice requires to be alkaline.* Moreover, if the experiments with the pepsin and pancreatin be kept going side by side, and be carefully watched, two further differences between the digestive agents will be observed. In the tumbler containing the peptic ferment, any fat present will be found floating on the surface of the liquid, and starch will remain unaltered; but in the tumbler with the pancreatic ferment, these as well as the meaty constituents of the food will be found to undergo change. Moreover if the two ferments be left for many hours at work, the tumbler containing the pancreatic ferment will by and by give off an unpleasant odour, showing that the pancreatic juice not only converts all the varieties of food into a condition in which they are fitted to enter the blood, but is capable of acting upon them still further and decomposing them into simpler bodies. In short, a putrefactive change follows that of digestion, which does not occur in the case of pepsin. These facts serve to point out two conditions for the use of the preparations of the pancreas in indigestion.

The first is that it is of little or no use to give pancreatin or liquor pancreaticus by the mouth in a mixture, as one administers pepsin, because as soon as it reaches the stomach it is plunged among an acid fluid and is, therefore, inert. It is possible that it may pass through the stomach unaltered, and when it reaches the small intestine, and the food becomes there alkaline by admixture with the bile, that it then becomes active. But at any rate it is plain that it is useless to give it with the expectation that it will aid digestion *in the stomach.*

When it is given with the desire of reaching the small bowel, it should be given with soda *two hours after a meal.*

The second fact indicated concerning pancreatic preparations is that they will be specially useful for digesting foods previous to administration, since they may be mixed with any kind of food, acting upon all kinds. All that is needful is to mix the liquor pancreaticus *and a pinch of bicarbonate of soda* with the food and keep it warm. Care must be taken that the ferment is not allowed to act too long before the food is to be used, else the food will have acquired an unpleasant bitter taste and perhaps an odour of decomposition. This may be avoided by using the food a short time after the ferment has been added, 20 to 30 minutes, or by boiling the food after that interval, which destroys the ferment, hinders any further action, and, therefore, permits the food to be kept as long as may be necessary.

A few directions for the use of liquor pancreaticus, the most commonly used preparation, may here be given.

For Milk.—To four tea-cupfuls of milk add one tea-cupful of cold water, divide the mixture into two equal parts, bring one-half to the boiling point, then mix the boiling portion and the cold portion together. This gives the mixture a temperature favourable to the action of the ferment. Now add a tea-spoonful of liquor pancreaticus and a good pinch (15 grains) of bicarbonate of soda: stir the mixture, and set it aside in a warm place (where it will simply be kept warm, without being made hotter) for 30 minutes. Then boil, and use as required.

For Tapioca, Rice, Sago, Corn-flour, Porridge, Gruel, or similar preparation.—Make the tapioca, gruel, or whatever it may be in the usual way but very thick. Mix thoroughly a tea-cupful of the food, when quite ready and boiling hot, with the same quantity of cold milk. Then add one or two tea-spoonfuls of the liquor pancreaticus and the large pinch of soda; mix well; set in a warm place for 20 to 30 minutes. If the solution is acting properly, the thick mixture will become perfectly fluid, and it may be immediately supped, as it is, or after being boiled.

For Beef or Chicken Tea.—The lean beef or chicken should be scraped down into a pulp, as

ordered for beef-tea (see p. 627), mixed with the proper quantity of water, and brought up to a blood-heat (100° Fahr.). Then stir in 2 or 3 tea-spoonfuls of liquor pancreaticus with half a tea-spoonful or thereby of bicarbonate of soda—that is to 1 lb. of meat scrapings and 4 breakfast-cupfuls of water. Keep the mixture at the temperature named for 1 hour or 1½ hour, tasting it from time to time, however, to see that the action of the ferment is not proceeding too far to the development of a disagreeable flavour; after a sufficient time boil, and use as required. If it is desired to thicken the beef-tea with flour, arrow-root, &c., such should be separately prepared, properly boiled, and then added to the cold meat and water, and when a proper temperature is secured, the ferment is added. The starch of the arrow-root, &c., will thus also be acted on. These directions will enable one to prepare and artificially digest almost any kind of food. It may be added that the London chemists, Burroughs, Welcome, & Co., put up their pancreatic powder, called zymine, in glass tubes along with the necessary soda, in quantity sufficient for the predigestion of one pint of milk. They are called **peptonizing powders.**

Liquor pancreaticus is especially valuable for adding to preparations of food used for injecting into the bowel in cases where food cannot be taken by the mouth. Thus milk may be prepared lukewarm with the addition of two tea-spoonfuls of the liquor and a large pinch of soda, and injected. A mixture of boiled arrow-root and strong beef-tea with the liquor pancreaticus and soda may be similarly used (see p. 873, for other nourishing injections).

Papain is a digestive ferment derived from the juice of the papaw-tree, *Carica Papaya.* It acts on albuminous food like pepsin. "The fruit of the papaw-tree has long been used in the West Indies to render beef tender. The unripe fruit is split open and rubbed over the surface of the meat previous to cooking."

Uses.—Papain is not very extensively used for indigestion, though it is useful in cases to which pepsin is applicable. It has been more largely used to dissolve warty growths and false membranes. The author has found it dissolve the false membrane of diphtheria with great rapidity in several cases. The solution recommended contains 12 grains of papain, 5 of borax, and 2 drachms of water, and it is painted on with a camel-hair pencil twice daily or oftener. In one or two days the membrane comes away on the brush in large portions. In urgent cases it might be used every hour or even oftener.

Ingluvin is a special American preparation, said to be prepared from the gizzard of the domestic fowl. Though recommended as a substitute for pepsin it has not been shown to have much action on coagulated egg albumen. It has been recommended specially for obstinate vomiting, and in particular for the vomiting of pregnancy. The dose is from 5 to 10 grains.

Lactopeptine is another preparation of ferments vaunted in the treatment of dyspepsia and other chronic affections of the stomach. Its dose is 10 to 15 grains.

Remedies for Flatulence of the Stomach.

The distension of the stomach with wind is a consequence of some kind of improper digestion. If the proper fermentive process does not take place, changes of decomposition occur, with the development of gas, and painful distension results, which by pressure interferes with neighbouring organs and specially the heart. The obvious remedy for this state of things is that which will correct the error of digestion, for if natural digestion be restored the production of gas will not occur. To this end probably the alkaline tonic with aromatic spirit of ammonia and a bitter tonic (see p. 844) taken before food would be useful. But while the discomfort and pain of the flatulence are present, the desire is for some means of exciting the stomach to expel the wind. There are many drugs which do this, but it is well to insist on the fact that they can afford only temporary relief. They dispel the wind at the time, but they give no guarantee that an hour or two after the next meal the same state of things will not be repeated. Every sufferer in this way ought, therefore, to seek to find some more permanent relief by finding some remedy for the improper digestion which is the cause of the disturbance. Substances which aid in the expulsion of gas from the stomach do so by stimulating the movements of the stomach wall, and it may be causing the communication between the lower end of the gullet and stomach to dilate so as to allow of the escape of the gas. Such substances are called **carminatives,** and they are usually aromatic substances such as allspice, anise, assafœtida, camphor, cinnamon, cloves, cayenne, caraway, cardamoms, coriander, dill, ginger, horse-radish, mace, mustard, nutmeg, pepper, peppermint, valerian, and stimulants, like ether alcohol and chloroform, and ammonia.

We shall give a list of the chief of their preparations and doses, and shall afterwards consider a few of them in more detail.

	DOSE.
Oil of Anise	2 to 5 drops on sugar.
Essence of Anise	10 to 20 drops.
Water of Anise	½ to 1 tea-spoonful.
Tincture Assafœtida	½ to 1 tea-spoonful.
Fœtid Spirit of Ammonia—Assafœtida 1½ ounce, strong solution of Ammonia 2 ounces, Spirit (proof) 20 ounces	½ to 1 tea-spoonful.
Pill Assafœtida	1 to 2 pills.
Compound Assafœtida Pill	1 to 2 pills.
Enema Assafœtida	30 grains powdered Assafœtida in 4 ounces of water.
Oil of Cajuput	1 to 3 drops.
Spirit of Cajuput	30 to 60 drops.
Camphor Water	1 tea-spoonful.
Oil of Caraway	2 to 5 drops.
Water of Caraway	1 to 2 ounces.
Compound Tincture of Cardamoms	½ to 2 tea-spoonfuls.
Tincture of Cayenne	2 to 10 drops well diluted.
Cinnamon Water	1 to 2 ounces.
Oil of Cinnamon	1 to 4 drops.
Compound Cinnamon Powder (Aromatic Powder)	3 to 10 grains.
(Equal quantities of Cinnamon, Cardamoms, and Ginger.)	
Tincture of Cinnamon	½ to 2 tea-spoonfuls.
Oil of Cloves	1 to 4 drops.
Infusion of Cloves	1 to 2 ounces.
Oil of Coriander	2 to 5 drops.
Powdered Coriander	20 to 60 grains.
Oil of Dill	1 to 4 drops on sugar.
Dill Water—The best for children	1 to 4 tea-spoonfuls in water.
Fennel Water	1 to 2 ounces.
Ginger Powder	10 to 20 grains.
Essence of Ginger	5 to 20 drops.
Syrup of Ginger	1 to 4 tea-spoonfuls.
Tincture of Ginger	10 to 30 drops.
Compound Spirit of Horse-radish	1 to 2 tea-spoonfuls.
Oil of Nutmeg	2 to 6 drops.
Spirit of Nutmeg	30 to 60 drops.
Oil of Pimenta (Allspice)	1 to 3 drops.
Pimenta Water	1 to 2 ounces.
Peppermint Water	1 to 2 ounces.
Oil of Peppermint	1 to 5 drops.
Essence of Peppermint	10 to 20 drops.
Spirit of Peppermint	15 to 30 drops.
Oil of Spearmint	1 to 5 drops.
Water of Spearmint	1 to 2 ounces.
Spirit of Spearmint	5 to 20 drops.
Infusion of Valerian	1 to 2 ounces.
(120 grains Valerian Root infused for 1 hour in ½ pint of boiling water.)	
Tincture of Valerian	1 to 2 tea-spoonfuls in water.
Ammoniated Tincture of Valerian	½ to 1 tea-spoonful.
Aromatic Spirit of Ammonia (see p. 843).	

These substances act by exciting the circulation in the stomach, causing a sense of heat and increased appetite, and aiding the digestion of food. They excite the nerves and relieve pain, and by stimulating the muscular movements of the stomach help to expel wind. An excellent combination for this would be half a tea-spoonful of aromatic spirits of ammonia, a few drops of tincture of cayenne, and a tea-spoonful of bitter infusion in half a wine-glassful of water.

Most of these remedies are also useful in the relief of spasm or cramp of the stomach or bowels. This consists in irregular and excessive contraction of part of the muscular wall of the intestinal tube. The remedy relieves it by exciting the natural movement as a whole, causing expulsion of the cause of irritation. These remedies are, therefore, also called **anti-spasmodics**.

Assafœtida as used in medicine is a gum resin obtained from the root of *Narthex assafœtida*, an umbelliferous plant, native of Persia, Afghanistan, and the Punjaub.

It is a powerful stimulant to the nervous system, very valuable for the relief of spasm, specially of a hysterical kind. Its unpleasant odour is the only objection to giving it for relief of flatulent distension of the stomach. This objection is overcome in the case of the bowels by giving it as an enema (see p. 874). It is valuable in hysterical affections at the period of change of life; and its antispasmodic effects are likewise available in whooping-cough, asthma, and other nervous diseases.

Anise, the fruit of *Pimpinella anisum*, **Fennel,** the fruit of *Fœniculum dulce*, imported from Malta, **Dill Fruit,** the dried fruit of *Anethum graveolens*, **Caraway,** the dried fruit of *Carum Carui*, **Coriander,** the dried ripe fruit of *Coriandrum sativum*, are substances all belonging to the same natural order—*Umbelliferæ*, and all yielding preparations which have similar effects on the body and are used for similar purposes.

They have all a stimulating effect upon the stomach and bowels. They may be used alone to relieve flatulence, and one or other is commonly given along with purgatives to diminish any tendency to griping. Anise and dill are specially used for children, for whom they are very useful.

Cloves belong to the *Myrtaceæ* order of plants and may be taken as a representative of this class of remedies. From all of them an aromatic essential oil may be distilled, which possesses the chief qualities of the remedy. These essential oils, when applied to the skin,

redden it, causing smarting at first, but later diminishing the sensibility of the part. They prevent decomposition. When taken internally, they act upon the mucous membrane of mouth, gullet, stomach, and bowels, as they act upon the skin, producing stimulation of nerves, exciting a freer flow of blood, causing increased appetite, and increased digestive power, relieving pain, hiccup, &c., and aiding in the expulsion of wind. Oil of cloves is used as an application for toothache because of its soothing effects following the first stimulating effect.

Cajuput is derived from the leaves of *Melaleuca minor* or cajuput-tree, growing in the Molucca Islands, the oil being imported from Batavia and Singapore. It and **allspice** or pimenta belong to the same order as cloves, and have similar actions.

Cardamoms and **Ginger** belong to the same natural order (see p. 594). They are both of them widely used as remedies for flatulence, usually in combination with other medicines, such as tonics. For example, the compound tincture of cardamoms or the tincture of ginger would be a useful addition to a tonic for indigestion.

Camphor is a solid volatile oil, obtained from the wood of *Camphora officinarum*, belonging to the same order as cinnamon, Lauraceæ. Rough camphor is imported from China and Japan and is re-sublimed in England.

Use.—It stimulates the skin and is a powerful irritant to raw surfaces and to mucous membranes. On this account it is employed for liniments and oils, as applications to sprains, painful and enlarged joints. It is destructive to low forms of animal life, and is used, therefore, for antiseptic purposes, along with carbolic acid, for decayed teeth, &c. It is its stimulating properties that make it useful, when taken internally, for flatulence and diarrhœa, in hysterical vomiting and the early stage of cholera. But when given in large doses it produces sickness and vomiting, by its irritant effects. It also stimulates the heart and circulation, when taken internally, and the nervous system. Because of its stimulating effects on the nervous system, it has been given in prostration of fevers, in poisoning by opium, and in various nervous affections. In overdoses it produces a species of intoxication, with confusion of speech and mind, and later convulsions. It stimulates the air-passages also, and is frequently used in combination with other substances as a cough mixture, and it acts also on the skin. In common cold-in-the-head it has been found useful when inhaled as a vapour, 30 to 60 grains in ½ pint hot water.

Its chief preparations are:—

	Dose.
Camphor Water	1 tea-spoonful.
(Place 30 grains crushed camphor in a small muslin bag in 1 pint of water for 2 days.)	
Spirit of Camphor	10 to 30 drops.
Compound Tincture of Camphor	15 to 30 drops.
(Contains opium—used for cough, and called Paregoric Elixir.)	

Cinnamon (see p. 595) is specially useful in combination with drugs for diarrhœa, because, besides its aromatic oil, it contains tannic acid properties, and has therefore an astringent as well as a stimulating action on the stomach and bowel.

Peppermint (see p. 594) is one of the most common remedies for flatulence and colic, either alone or in combination with purgatives, or, in cases of diarrhœa, with astringents. Rubbing the skin of face and hands and other exposed parts with soap strongly scented with peppermint or lavender prevents mosquito bites. Hanging a sprig of the plant or of pennyroyal near the head during sleep is said also to be useful, or a small bottle containing the volatile oil.

Spearmint has similar properties to peppermint.

Valerian—the dried roots and rootlets of *Valeriana officinalis,* plants growing wild and cultivated in Britain. The preparations of valerian have a strong stimulating effect upon the stomach and bowels, heart and nervous system. It is specially used for hysterical flatulence, fainting, palpitation, and convulsions. In large doses the oil paralyses the nervous system.

Besides these remedies creasote, sulphurous acid, and carbolic acid have been given for flatulence, and also charcoal. The idea of using the three former substances is that they prevent changes of decomposition occurring which may be the cause of the flatulence. They may be tried in drop doses diluted. The object of using charcoal is to diminish distension by the absorption of the gas. For this purpose a half tea-spoonful of the powder may be used.

Emetics.

These are substances which cause the stomach to expel its contents by way of the mouth (Greek *emeo,* to vomit). Some substances produce this action by influencing the stomach itself, by an irritating effect upon its walls. This is the way in which mustard acts, for example, car-

bonate of ammonia in large doses, infusion of chamomile flowers, salt and water, sulphate of zinc, alum, and sulphate of copper. Large draughts of warm water act by their mechanical bulk. These are called **direct emetics.** On the other hand there are a few drugs which excite vomiting by acting on the nervous system, and may produce their effect without entering the stomach at all, such as, among others, tartar emetic, ipecacuanha, apomorphia. That vomiting may be principally dependent upon nervous changes is shown by the fact that mere impressions upon the nerves of sight, taste, smell, may excite it, or the mere idea or recollection of such impressions, as the recollection of a disgusting smell or sight, &c., and by the fact that vomiting is a very common symptom in irritation of the brain, as in inflammation of the membranes of the brain, and the pressure of tumours or effusions on the brain. Then the induction of vomiting by tickling the throat with a feather, or by passing the finger into the throat, is an illustration of reflex nervous vomiting. The occurrence of vomiting in disease of kidneys, ovaries, womb, &c., is another illustration of the same thing, the stomach being acted on by nervous impressions conveyed from the diseased organ.

It is to be noted that vomiting is not a simple act of expelling the contents of the stomach. Other organs are influenced more or less, according to the nature of the agent used to excite the act. Usually there is general depression, enfeeblement of the circulation, weakening of the action of the heart, languor, and muscular weakness. The air-passages are affected, air being pressed out of the lungs by the compression of the abdomen. In bronchitis, croup, and other diseases of the air-passages, this effect is beneficial by clearing the tubes of phlegm, &c. Often, moreover, the emetic used has a stimulating action upon the respiratory passages, such as ipecacuanha, so that the sweeping out of material from the lungs is more effectually secured. The act of vomiting is also accompanied by increased secretion of sweat, saliva, and mucus from the glands of the throat and air-passages. The pressure exerted upon the abdomen in the act of vomiting expels bile from the gall-bladder, and is sometimes made use of to get rid of gall-stones lodging in the bile-duct. Now it will be understood that the additional effects on the heart and circulation, lungs and nervous system, are much more marked in the case of drugs which act through the general system, and much less marked, or not marked at all, in the case of emetics acting simply locally on the stomach. Mustard and water given for the purpose of emptying the stomach and getting rid of a mass of ill-digested and irritating food will rather produce a sense of comfort and well-being than a feeling of depression. Tartar emetic, on the other hand, produces great depression, and might cause serious weakening of the circulation and collapse in delicate persons. Therefore, in selecting an emetic, one ought to consider the other effects the emetic may produce, and whether it is advisable, in the particular case, to risk them or not. The mere increased pressure upon certain organs, specially upon the lungs and blood-vessels, must not be forgotten, and it will show the need of refraining from the use of such substances in the case of persons with weak blood-vessels, liable to attacks of bleeding.

We will now consider some of the details connected with the action of the drugs used as emetics.

Lukewarm Water given in large draughts is one of the simplest and safest of emetics, and may be used to rid the stomach of irritating masses of food, in sick headache, or to aid in the expulsion of some piece of food lodged in the upper part of the gullet. Salt and water, a table-spoonful in a tumbler of warm water, are also employed for a like purpose.

Mustard and Water.—One or two tea-spoonfuls of mustard to a tumblerful of hot water is more expeditious than simple lukewarm water, and is employed under similar circumstances. It is the means most ready to hand in cases of poisoning, and in cases of laudanum-poisoning it is to be preferred to sulphate of zinc or copper, since the laudanum may so deaden the susceptibility of the stomach walls that it is impossible to induce vomiting, and the use of the stomach-pump may be necessary. In such a case the substance given as an emetic remains in the stomach and may be absorbed. In the case of mustard no harm will be done; in the case of zinc, &c., harm might arise.

Infusion of Chamomile Flowers.—Emetic dose, 5 ounces or upwards. See p. 840.

Carbonate of Ammonia.—30 grains in water, as an emetic. See p. 843.

Zinc.—The chief preparations of zinc used as emetics are as follows:—

Sulphate of Zinc....	Emetic dose,	10 to 30 grains.
Acetate of Zinc.......	,,	10 ,, 20 ,,

Sulphate of zinc is employed as an emetic when an effect is speedily desired. Besides rapidity of action, very necessary in cases of poisoning, it possesses the property of producing

little depression. It is chiefly in cases of poisoning it is employed.

Preparations of zinc are also employed for their tonic and astringent properties, and are considered further on p. 869.

Copper.—

Sulphate of Copper.........Emetic dose, 5 to 10 grains.

Preparations of copper are chiefly used for external application, but some of its salts are noted on p. 869 later in this section. As an emetic the zinc sulphate is preferred.

Alum.—

Dried Alum......Emetic dose, 30 to 60 grains.

Alum is mainly used as a local application, for washes, gargles, &c., and is considered further on in this section (p. 868).

Ipecacuanha belongs to that class of emetics which act upon the general system. It will be suitable here to consider all its actions upon the body, and the chief preparations. The plant is called the *Cephaëlis Ipecacuanha*, and it is the dried roots that are used. These are dull-gray, bent and twisted, with a thin, white, finely-porous core, and a thick wrinkled bark, presenting the appearance of a series of rings threaded on to the core. The root is powdered, and besides starch, gum, &c., contains the active principle emetin and ipecacuanhic acid, a substance allied to tannic acid.

Preparations:—

	DOSE.
Powdered Ipecacuanha	½ to 2 grains as expectorant. 15 to 30 ,, emetic.
Ipecacuanha Wine....	5 to 40 drops as expectorant. 3–6 tea-spoonfuls as emetic.
Compound Ipecacuanha Powder (Dover's Powder) (1 grain of Ipecacuanha, 1 grain of Opium, 8 grains Sulphate of Potash), .	5–10 grains (*for adults only*).
Syrup Ipecacuanha (an American preparation)	2 to 30 drops as expectorant. ½ to 1 ounce as emetic.

Ipecacuanha powder has marked irritating properties. Dust of ipecacuanha in process of grinding gaining entrance to the nostrils, and air-passages in general, produces all the symptom of a severe cold in the head, sneezing, swelling of the lining membrane of the nostrils, coughing, and a species of hay-asthma; and it may even produce a pustular eruption. When the wine is used as a spray to the throat, its stimulating qualities cause increase of the secretion of the throat glands, and relieve dryness of the parts and cough and irritation arising therefrom. Taken into the stomach it produces similar effects. If the dose be small, it acts as a stimulant to the stomach, and produces frequently marked beneficial results by the stimulus, specially in catarrhal conditions of that organ. In larger doses it excites sickness and vomiting by the marked irritation it produces. It acts very quickly, and for this purpose a good method of administration consists in giving 5 grains of the powder in water every 5 minutes till the effect is produced. Gaining entrance to the blood, it acts on the lining membrane of the air-passages, increasing the phlegm, and rendering it more fluid. It is thus specially in cases where the expectoration is scanty or tough and expelled only with difficulty that ipecacuanha should be employed. It is widely used in bronchitis of children to aid in the removal of the phlegm, and in whooping-cough also. It acts also on the skin, and in common colds, in combination with opium as Dover's powder, it is one of the best of remedies. It is employed also for its effect on the liver by increasing the secretion of bile, and for its stimulating effects on the bowel in dysentery. Its praises have been sung in the acute dysentery of the tropics. For this purpose it must be given in large dose—30 to 90 grains, and it is said such doses may be given in this disorder without inducing vomiting, if the patient will keep lying quietly on the back. In suitable cases the motions become natural in character and frequence, and straining and griping disappear. After a large dose—60 to 90 grains—a second will not be required for 10 to 12 hours, if any second be needed at all. Instead of being given by the mouth it may be injected into the bowel—30 to 60 grains suspended in a small quantity of gummy fluid, three or four times a-day. It is also worth trying in the diarrhœa of children, when the stools are slimy and green. One or two drops of the wine every hour are recommended; and all the more if vomiting also be present. It may appear strange that a drug given to produce vomiting should also be able to allay vomiting, but it appears to yield much relief in some forms of the vomiting of pregnancy, that form which occurs soon after waking, and also in those cases where sickness, heartburn, and flatulence are associated. One drop of the wine every hour or several times a-day is recommended by Ringer for this purpose, and for the morning sickness of drunkards. The vomiting due to cold-in-the-stomach—gastric catarrh—which is frequently also attended by purging, will almost certainly be relieved by a dose of the Dover's powder, repeated in 3 or 4 hours. A spray of ipecacuanha wine is highly

recommended by Dr. Ringer to relieve the cough, tightness of the chest, and difficult breathing of "winter cough." The person should breathe deeply at every squeeze of the spray-ball to get the vapour well into the air-passages, and two or three squeezes should be used at each sitting, and repeated twice daily or so.

Emetin, the active principle of ipecacuanha, is used as an expectorant in doses of $\frac{1}{200}$ grain and as an emetic in doses of $\frac{1}{6}$ to $\frac{1}{3}$ grain. It is very powerful, and not to be used except by medical orders.

Tartar Emetic—Antimony.—Antimony is a metal. It is not employed in medicine in its metallic state. Its chief preparations used in medicine are:

Tartar Emetic or Tartrated Antimony....	Dose,	as an expectorant $\frac{1}{16}$ to $\frac{1}{6}$ grain, as an emetic 1 to 2 grains.
Antimonial Wine..................................	,,	to cause sweating 10 to 40 drops, as an emetic $\frac{1}{2}$ to 1 teaspoonful repeated.
James's Fever Powder (1 part of Oxide of Antimony with 2 of Phosphate of Lime).	,,	3 to 10 grains.

Another preparation of antimony, the "butter of antimony," properly the solution of the chloride of antimony, is used by veterinary surgeons for application to foul sores and malignant surfaces to cleanse them. An ointment of tartar emetic (1 of tartar emetic to 4 of lard) is used for enlarged joints, in cases of neuralgia, and as a stimulating application to the chest in bronchitis, whooping-cough, &c.

Uses.—The ointment of tartar emetic applied to the skin reddens it and brings out a crop of pimples which become pustules. It is irritating, that is to say. Now when tartar emetic is taken into the stomach in *small quantity*, it is mildly irritating, producing a feeling of warmth at the stomach; sweating also follows. In slightly larger doses the irritating action produces loss of appetite, sickness, weakness of the circulation, and a feeling of feebleness and depression. At the same time the secretion from the glands of the stomach, bowels, respiratory passages, and skin is increased. After larger doses vomiting occurs with great weakness and depression and muscular relaxation, and after poisonous doses the symptoms of irritation of stomach and bowels are marked. There occurs diarrhœa, the pulse is small and quick, and the skin is covered with cold clammy sweat. The symptoms are very like those of cholera, cramps of the extremities also occur, and before death sometimes delirium and convulsive spasms.

Tartar emetic is used chiefly for its emetic and depressing properties, but it is not resorted to now nearly so much as formerly. On account of its marked effect in reducing the strength and frequence of the pulse it used to be much employed at the beginning of fevers, and during the course of acute inflammations of lung, bowels, brain, &c. Its effect in stimulating the skin made it still more useful in these conditions. For these objects, however, it is scarcely now employed, except in acute inflammations in otherwise perfectly healthy and robust persons. To cause vomiting in order to get relief in bronchitis or croup or whooping-cough, ipecacuanha is preferred. Emetics have been found very useful to cut short attacks of malarial fever, such as ague, when accompanied by a purgative and followed by the administration of quinine.

Antimony in any of its forms should never be administered to the very young, very old, or feeble; and indeed what has been said ought to be sufficient to deter unskilled persons from its use.

Plummer's Pill is a mixture of calomel, sulphurated antimony, guaiacum resin, and castor-oil, and the presence of the antimony is supposed to increase its stimulating effect upon the liver, causing an increased outpour of bile into the bowel.

The use of antimony sometimes brings out a pustular eruption on the skin.

Poisoning by antimony is to be treated by administering solutions of tannin, easily obtained from strong infusions of tea, or oak-bark, or cinchona. Stimulants ought also to be given to relieve depression, diffusible stimulants like ammonia being preferred.

Apomorphia is made from morphia by heating it in a closed tube with concentrated hydrochloric acid. It is one of the most certain of emetics, and causes neither irritation of the stomach nor diarrhœa. It induces vomiting, not by acting on the stomach, but by its influence on the nerve-centres, and as the dose is small it can be injected under the skin by the hypodermic method (see p. 813). The dose, when thus used, is $\frac{1}{20}$ to $\frac{1}{10}$ grain. If taken by the mouth, a dose of $\frac{1}{10}$ to $\frac{1}{6}$ grain is required. In a few minutes after injection there is sickness, not excessive, and free vomiting, and depression does not last long. Apomorphia is now employed when speediness of action is desired, as in cases of poisoning, and in cases of lodgment

of foreign bodies or masses of food in the gullet. It is not a substance, however, to be employed by any but a skilled person, and certainly not in the case of children, except by some responsible person who is well acquainted with the materials he is using.

Remedies which Soothe the Stomach.

All the substances which we have been hitherto considering in this section act as stimulants to the stomach, increasing the activity of its circulation, the energy of its movements, and the excitability of its nerves. It is very frequently necessary to produce quite contrary effects, to diminish the circulation, to quiet the churning movements, and to dull the nervous sensibility. Remedies which do this are called **gastric sedatives.** The indications for the need of such treatment are an excessive irritability, which causes the stomach to eject its contents by vomiting, or to threaten to do so, pain, and sometimes diarrhœa, caused by the food being hurried out of the stomach before it has time to be digested, a kind of diarrhœa which is recognized by its being almost invariably set up a very short time or only a few minutes after food is taken. Substances which thus soothe the stomach may do so directly. For example, if marked irritability of the stomach be due to excessive acidity of its contents, a few grains of bicarbonate of soda, by neutralizing the excess of acid, will procure relief and quiet down the organ. In like circumstances a glass of warm water is often sufficient to procure relief. Or if the irritability be due to flatulent distension, some of the agents for expelling wind—ginger, peppermint, &c.—may have a similar calming effect. This action is due to the direct influence on the stomach itself and its contents. On the other hand, other remedies act in a more general way, through the blood and nervous system. Opium is an excellent example of this class, acting as a sedative to the stomach by its effect upon the nerves.

Ice is the most powerful of local sedatives to the walls of the stomach. It is simple, and in cases of pronounced irritability, evidenced by the vomiting of everything taken, no matter how small in quantity, ice should be resorted to. The ice should be swallowed in small pieces, and milk ought to be iced and sips taken at frequent intervals. The application to the walls of the abdomen over the region of the stomach of mustard poultices will aid the treatment materially.

Bismuth is one of the chief local soothing agents in stomach irritability. Bismuth is a metal; its chief preparations are as follows:—

Carbonate of Bismuth	Dose,	5 to 20 grains.
Subnitrate of Bismuth	,,	5 to 20 ,,
Bismuth Lozenges	,,	1 to 6 lozenges.

2 grains of subnitrate in each lozenge.

Uses.—Bismuth in the form of subnitrate is used to allay irritation outside the stomach, as a dusting powder, wash, or ointment to chapped hands and nipples, and to weeping sores such as the raw surface of eczema. Used as snuff it is very valuable in the commencing stage of cold in the head, the stage when the irritability of the lining membrane is so great that sneezing is occasioned by the slightest movement of air. It is best combined with morphia and powdered gum arabic as Ferrier's snuff (see p. 155). In 10-grain doses the subnitrate, or still better the carbonate, of bismuth is one of the best remedies in irritable indigestion, of which pain squeamishness and vomiting are the signs. In the beginning of cold in the stomach—gastric catarrh—when everything is rejected, and there is headache, bone-pains, and feverishness, bismuth with opium in the form of Dover's powder commonly acts like a charm. If it is not desirable to give opium, for example to young persons or to those with whom opium disagrees, it may be combined with one of the preparations of lime or magnesia. A solution of bismuth is now obtainable from all chemists, which may be used for children, and the dose of which is from ½ to 1 teaspoonful for adults. The drug is as useful for irritable conditions of the bowel, diarrhœa, dysentery, &c., and specially for the diarrhœa coming on suddenly after a meal.

Dilute Hydrocyanic Acid.—A solution of prussic acid. Pure prussic acid is one of the most powerful poisons, a single drop let fall into the eye, nose, or mouth of a small animal killing it instantly by its action on the heart and breathing through the nervous system. The dilute acid contains 2 per cent by weight of the pure. Poisonous doses paralyse the brain, nerves, and muscles. If the strong acid be applied to the skin it renders the part numb, abolishing in it the sense of touch by passing through the horny layer and paralysing the sensory nerves, and the dilute acid, applied for a time, will produce a like effect. It is this action which renders it a valuable drug for depressing the sensibility of the throat and stomach and allaying irritability. When a dose of the weak acid is taken into the mouth it produces a dulling effect upon the throat and gullet, and a

soothing influence on the stomach. For these purposes the dose of the dilute acid is 2 to 8 drops.

Poisonous doses, not large enough to kill instantly, produce slowness of breathing, difficulty of breathing, symptoms of suffocation, and death, after convulsions, by suffocation, all this owing to paralysis of the nerve-centre presiding over the movements of breathing. Headache, mental confusion, and stupor are also among the symptoms. In cases of accidental poisoning the person must be taken into the cold air, artificial respiration must be used, and sluicing with cold water. Freshly-prepared oxide of iron along with carbonate of soda, potash, magnesia, or lime is an antidote.

Dilute hydrocyanic acid is never prescribed alone, but always in combination with other substances of a sedative kind, such as bismuth, solution of morphia, and so on. Besides in cases of irritable dyspepsia, it is used for dry irritable cough, and to relieve the hacking cough of consumption and the asthmatic cough. It is also employed as a wash, ½ ounce to 8 ounces of rose-water, for itching of the skin, or in combination with zinc ointment—30 to 60 drops to each ounce—for a like purpose.

Among other sedatives to the stomach are—**Belladonna** and its active principal **Atropine**, **Opium** and its active principal **Morphia**, which are discussed in the section devoted to Drugs Acting on the Nervous System.

Oxalate of Cerium is another drug, given in doses of 1 and 2 grains as powder for vomiting, specially the vomiting and heartburn of pregnancy. It is not, however, very reliable.

Chloroform, Ether, and Cocaine, discussed elsewhere, are also gastric sedatives.

Sulphurous Acid, Creasote, Carbolic Acid, in 1-drop doses in water, also allay irritability of stomach when it depends on processes of fermentation set up within the stomach.

Ice and bismuth with the outward application of mustard poultices are the remedies to be commonly employed for allaying stomach irritability, of course after any irritating substance has been expelled, and combined with the administration of bland soothing food, in small quantities.

DRUGS WHICH ACT ON THE BOWELS.

A large portion of what has been written in the previous part of this section is as applicable to the bowel as to the stomach itself. The bowel may be stimulated by the same means which stimulate the stomach, such means as excite a more lively circulation or a more vigorous movement, such as bitter and aromatic tonics. The same remedies which are useful in expelling wind from the stomach will help in dispersing it from the bowel, and the drugs which exert a sedative influence on the one will do so on the other also. Then the whole bowel will be markedly influenced by the state of the stomach. If the contents of the stomach have left it in an irritating, intensely acid, acrid condition, they will prove very irritating also to the small bowel, which they enter; and the acidity may not be sufficiently neutralized to allow of the digestion by the pancreas and the bile to go on satisfactorily. An ill-digested mass will consequently be passed along the bowel, producing irritation as it goes, ending, it may be, in irregular contraction of the bowels, colic, and hasty expulsion of the offending materials by a too copious discharge. This condition of affairs the administration of some alkaline medicine, soda or potash, while the food was still in the stomach, would have greatly diminished, if not prevented, by diminishing the excessive acidity. On the other hand, if, through weakness, the gastric juice has been deficient, the contents of the stomach have not been acid enough, the absence of the usual stimulus of the acid material passing over the openings of the bile and pancreatic ducts might lead to a diminished flow of the respective juices and to a continuance of the imperfect digestion already begun in the stomach. So that we may say the proper performance of digestion in the stomach is the necessary preparation for proper digestion in the upper part of the small intestine. There remain, then, for our consideration, two large classes of drugs affecting the bowel, namely those which assist in the expulsion of the remains of the food and other contents from the bowel, and those which restrain such an action, in short purgatives and astringents, remedies for constipation and for diarrhœa.

Remedies for Constipation: Purgatives, &c.

When one considers on what conditions the regular onward progress of the altered foods in the bowel depends, it becomes easier to understand in how great a variety of ways constipation may be produced and after how many different methods it may be treated. To the altered food as it passes along the bowel, there are added various juices, the bile, pancreatic juice, and intestinal juice, dependent as to quantity upon the blood supply to the organs manufacturing

them, and upon the stimulus received from the food itself. From this mixture of food and digestive juices there is being removed, in liquid form, as it passes along, much of its nutritive material, and the consistence of the mass in its onward progress will depend on the relation between the addition of fluid and the abstraction of dissolved nutriment. Defective secretion and slow progress will produce a very dry residue, little being added and as much as possible abstracted, while hurried progress will make a very fluid residue, because little time is given for absorption; and such hurried progress is usually the result of irritation, which will have, as another of its effects, a more copious secretion. The onward progress is due to the worm-like spiral wave of contraction that passes along the bowel always in one direction—the peristaltic movement, and this movement depends for its rate and its energy upon the excitability of the muscular wall of the bowel and on the state of the nerves between the muscular layers. It remains to be added that the bile, besides aiding the movement merely by its watery character, does so also by the stimulating action it has upon the bowel, increasing thereby the peristaltic contraction. It is plain, therefore, that the movement of the remains of food-stuffs along the digestive canal will be aided by any substance which (1) increases the quantity of the digestive fluids, or (2) drains water from the blood into the canal, or (3) increases specially the quantity of the bile, since it is particularly stimulating, or (4) increases the movement either by directly exciting the muscular walls, or indirectly by acting through the nerves. Now, there are drugs capable of accomplishing one or other of these actions, and some of them act at the same time in several of the ways indicated. Certain terms are employed to signify the special way in which the remedy acts. The general term for all the varieties of action is **purgative**, from Latin *purgo*, I cleanse, since the effect is to clear offensive material from the bowel. **Cathartic** is a term implying the same thing, being derived from the Greek *kathairo*, I purge. When the means used are such as to cause simply a movement of the bowel in the mildest possible way, without producing any marked effect upon secretions or the walls of the bowel, they are said to be **aperient**, from Latin *aperio*, I open, or **laxative**, from *laxo*, I loose. When the action produced is violent, the substance is said to be a **drastic purgative**, from the Greek *drastikos*, active. Now, ordinarily, purgatives act in more ways than one, they both stimulate the walls of the bowel to increased movement and they excite an increased secretion. But there are others which act specially in one direction. For example, substances like common salt, Epsom salts, rochelle salts, &c., all saline medicines, are particularly active in withdrawing water from the blood and producing copious watery stools, and such remedies are technically called **hydragogue cathartics** (from Greek *hudor*, water, and *ago*, I drive out). Again there are purgatives whose special action consists in increasing the flow of bile from the liver, and these are called **cholagogues** (Greek *chole*, bile, and *ago*); such are podophyllin, rhubarb, calomel, and aloes.

Laxatives or Aperients.

Many substances, not necessarily drugs, act in a mild way in aiding movement of the bowels. Foods which have some roughness when prepared, such as oatmeal porridge and bran bread, are suitable for this purpose. Substances also which have a large residue of undigested material help to a movement of the bowels by their mere bulk, such as vegetables and fruits, like prunes, figs, apples, &c., the vegetable acids of which are also agents in the process.

Castor-oil is the chief of laxative medicines. It is the oil expressed from the seeds of the castor-oil plant — *Ricinus communis* — which grows in America and the East Indies. The remains of the seeds, after the oil has been separated, contain a substance which has a violent purgative action. The castor-oil seeds, or beans, if taken themselves, produce severe inflammation of the bowel, shown by violent vomiting, purging, and collapse, even death. The oil contains almost none of the substance to which these effects are due. It is in small doses mild and non-irritating in action, and is, therefore, suitable for women, delicate persons, and children, and is always a useful agent when it is desired to move the bowels with as little disturbance as possible, as in irritable conditions of the bowel, in pregnancy, when piles or fissure of the anus is present, and in other similar circumstances. When taken by a nursing mother, it acts also upon the child through the milk.

In two opposite conditions it is specially valuable: first in that of simple constipation, where one desires simply to empty the bowel, and to produce no other effects, and second in diarrhœa. The type of diarrhœa in which it is specially useful is that dependent upon some irritating material in the bowel, ill-digested

food, for example. The castor-oil sweeps out the offending material, and thus allows the bowel to quiet down. In the diarrhœa of children, therefore, in particular that dependent upon some error in diet, specially apt to occur in summer, is castor-oil valuable.

Dose for adults, $\frac{1}{2}$ to 1 ounce.
,, children, 1 tea-spoonful and upwards.

For constipation it is best given in the morning, an hour before breakfast; given thus early, a small dose often suffices. From 15 drops to half a tea-spoonful may be tried. The spoon or glass in which it is to be dropped should be well wetted with water or peppermint water. Indeed, if a little peppermint water be taken in the vessel first, and the oil dropped upon it, the glass being kept in gentle motion to keep the sides wet and free from the oil, the oil may be swallowed down floating on the water, and leaving no taste. Lemon-juice, coffee, and milk are used on which to float the dose, or an equal quantity of glycerine may be added to the dose, and a drop or two of oil of cinnamon. Castor-oil is recommended to relieve painter's or lead colic. In threatened inflammation of windpipe and in bronchitis a dose affords much relief. It may be dropped into the eye to relieve the feeling of sand in the eye, and in cases of accidental burning of the eye. The leaves of the castor-oil plant have been used as a poultice to the breast to encourage the flow of milk.

Senna is also a much-used laxative medicine. It is the leaves of small shrubs belonging to the genus *Cassia*. There are several kinds, one Egyptian—Alexandrian senna, another Indian —Tinnevelly senna.

The preparations of senna are as follows:—

Infusion of Senna, (Senna leaves 1 oz., sliced ginger 30 grs., boiling water 10 ozs.; infuse one hour and strain.)	Dose, 2 to 4 table-spoonfuls.
Syrup of Senna,	,, $\frac{1}{2}$ to 4 tea-spoonfuls.
Confection of Senna contains, besides senna in powder, coriander, figs, tamarind, cassia pulp, prunes, extract of liquorice,	,, 60 to 120 grains.
Tincture of Senna,	,, 1 to 4 tea-spoonfuls.
Black Draught, or Compound Mixture of Senna, (Epsom salts 4 ozs., extract of liquorice $\frac{1}{2}$ oz., tincture of senna, $2\frac{1}{2}$ ozs., compound tincture of cardamoms $1\frac{1}{4}$ oz., infusion of senna enough to make up a pint.)	,, 2 to 3 table-spoonfuls.
Compound Liquorice Powder, made of 1 oz. powdered liquorice root, 1 oz. of senna, and 3 ozs. of sugar,	,, 30 to 60 grains.

Senna acts briskly on the bowel, increasing both the movement and the secretion from the walls of the bowel. It acts chiefly on the small intestine, and not on the large intestine. This contrasts it with aloes, which acts principally on the large bowel. It is apt to cause sickness and griping, but this is avoided by combining it with other drugs, such as Epsom salts, and as illustrated in the compound senna mixture. Senna taken by a nursing mother will affect the child. It should not be given when any irritability of bowel is present. The syrup is a pleasant opening medicine for children; and the compound liquorice powder is very largely used for simple constipation.

Sulphur also belongs to the laxative group of medicines, because of its stimulating effects on the wall of the bowel. The preparations and other uses of sulphur and its compounds are stated at length on p. 826. For the laxative effect the old-fashioned sulphur electuary is the best form for administration.

Tamarind.—The preserved pulp of the fruit of the Indian tamarind is a pleasant and effective medicine. The *Tamarindus indica* is a tree 60 to 80 feet high, indigenous to India and tropical Africa, belonging to the natural order Leguminosæ, the same order as the pea and bean. The fruit is a pod about 6 inches long and 1 inch broad, containing an acid pulp, in which the seeds, nine to ten in each pod, are embedded. The West Indian fruit is shorter in pod. The pod is inclosed within a thin pale-brown shell, which is removed for purposes of preservation, and then the soft pods are pressed into a mass, to which sugar is sometimes added. In Upper Egypt the soft pulpy mass is formed into cakes, and dried in the sun; in the West Indies hot syrup is poured over the pods. From the fresh leaves and flowers of the tamarind cooling acid drinks are prepared.

Tamarinds contain citric, tartaric, and malic acids to the extent of over 10 per cent, also cream of tartar is present to the extent of $3\frac{1}{4}$ per cent, and nearly 24 per cent of sugar, gum, and pectin. Woody fibre forms over 34 per cent, and water $27\frac{1}{2}$ per cent.

Purified tamarind pulp is prepared by making a semi-liquid mass of East Indian tamarinds with boiling water, passing the whole through

a hair sieve, and then evaporating the fine pulp obtained to a proper thickness and adding a fifth of its bulk of powdered sugar. The prepared pulp is employed in the making of confection of senna.

Tamar Indien is a kind of laxative sweetmeat. It consists of compressed tablets of tamarind pulp to which some purgative has been added, perhaps senna or jalap, and which is flavoured with other materials.

The quantity of tamarinds necessary for laxative effect is ¼ oz.

Besides being laxative, tamarind, because of the acids and cream of tartar it contains, is useful for diminishing thirst, is cooling, and useful in feverish conditions. For drinking purposes **tamarind whey** is the form of employment. It is prepared by boiling 1 oz. of tamarind pulp with a pint of milk and then straining and filtering, and a simpler drink may be made by adding 4 ozs. of tamarinds to 100 ozs. of boiling water, straining, filtering, and allowing to cool.

Buckthorn is another mild opening medicine in common use as a syrup. The buckthorn is a branching shrub about 9 feet high, growing in thickets in Europe and Siberia, native to Britain, and cultivated to some extent for hedges in North America. It belongs to the natural order Rhamnaceæ. There are several allied plants employed as laxatives in medicine, all of which may be noted here. The **common buckthorn** is *Rhamnus catharticus.* The ripe berries are employed to yield a juice—Buckthorn juice, which is used only in the manufacture of the syrup of buckthorn. There is the **alder buckthorn** or black alder, a shrub 10 to 15 feet high, the proper name of which is *Rhamnus Frangula.* The dried bark, frangula bark, is employed as a domestic purgative in Germany. A decoction of it is prepared with ½ oz. of bark and ½ pint of water and given in table-spoonful doses. There is a recognized extract of frangula bark and a liquid extract. The bark should be kept at least a year before being used; when it is fresh it has too irritating properties.

A third kind of allied plant is the *Rhamnus Purshiana* found on the Pacific slopes of North America. It is a small tree, 15 to 20 feet high. The bark is used to yield an extract. On the Pacific coast it is called **Chittem-bark**, and is now more commonly known as **Cascara Sagrada**, or sacred bark.

The commonly used preparations of these varieties of the buckthorn species are as follows:—

	DOSE.
Syrup of Buckthorn, ...	½ to 4 tea-spoonfuls.
Fluid Extract of Frangula Bark,	1 tea-spoonful.
Extract of Frangula Bark,.....	15 to 60 grains.
Liquid Extract of Cascara Sagrada, ...	10 to 60 drops.

Uses.—Syrup of buckthorn is much used as a domestic remedy for children. It acts quickly but is apt to be accompanied with some griping. The liquid extract of cascara sagrada is, however, very extensively used in cases of habitual constipation, not as a purgative, but simply to secure no more than a natural motion. For this purpose the person troubled with habitual constipation should find the dose that is just sufficient to secure an ordinary motion. He should begin with 30 drops, which may be taken flavoured in any way he pleases. If that is not enough, a tea-spoonful may be tried; if it on the contrary acts too strongly, 15 drops may be sufficient. But let the exact quantity be determined, and then let that quantity be taken regularly once a day, at bed-time or on rising in the morning. A smaller dose is likely to be sufficient, if taken in the morning on an empty stomach, but some people prefer to take the medicine at bed-time, and it is then likely to act after breakfast, and so inconvenience during the day is avoided. After taking the drug regularly in this way, each day for a fortnight or three weeks securing a regular motion, the effort may now be made to diminish the medicine. It is still to be taken daily with perfect regularity but in gradually diminishing doses. Thus, if 15 drops have proved sufficient, 14 drops may be taken. If it is still sufficient, after several days 13 drops may be used, and so on. For with habitual use of cascara sagrada, unlike ordinary purgative medicine, a tonic effect on the bowel is produced, and smaller doses begin to have the required influence. In time the constipation may thus be completely relieved, and the use of medicine discontinued.

Dandelion Root.—The fresh and dried roots of *Taraxacum Dens Leonis* gathered between September and February from meadows and pastures in Britain. Its preparations are:—

Decoction of Dandelion,	Dose,	2 to 4 ounces.
Extract of Dandelion, ..	,,	5 to 15 grains.
Dandelion Juice, ...	,,	2 to 4 tea-spoonfuls.

Uses.—Dandelion was believed to stimulate the flow of bile directly. It appears, however, that it promotes the flow of bile only by its slightly opening effect, and that its chief value is as a tonic and mild laxative. It may be given in cases of habitual constipation and weak

digestion, and is usefully combined with the dilute nitro-hydrochloric acid when liver symptoms are prominent. It sometimes acts upon the kidneys.

Other drugs used as laxatives are:—

Glycerine in a dose of 1 to 2 tea-spoonfuls.
Light and Heavy and Carbonate of Magnesia (see p. 843).
Manna (see p. 590).
Olive-oil, ... Dose, 1 to 2 tea-spoonfuls.
Almond-oil, ... ,, ,, ,,

Simple Purgatives.

These are substances which act more strongly than the mere aperients or laxatives, owing to a more pronouncedly irritating effect upon the walls of the bowel. On this account they are likely to be attended with some amount of griping, and they produce more liquid stools, acting, it may be, more than once. Some of the drugs already named under the laxatives act as simple purgatives if given in larger doses, such as senna, buckthorn, and castor-oil. The chief of the simple purgatives are rhubarb and aloes.

Rhubarb is the dried root of a plant obtained in China, Chinese Tartary and Thibet, and imported from Shanghai and Canton. It was known as a purgative in China from time immemorial, the earliest accounts of it coming through Arabian writers. Its name is derived from that of the river Rhâ—the Volga—from which direction it came to the countries bordering the Levant. Its chief preparations are as follows:—

	DOSE.
Tincture of Rhubarb, ...	1 to 8 tea-spoonfuls.
Wine of Rhubarb, ...	1 to 2 ,,
Syrup of Rhubarb, ...	1 to 4 ,,
Powdered Rhubarb Root, ...	10 to 30 grains.
Gregory's Powder (Compound Rhubarb Powder), ..	30 to 60 ,,

(Powdered rhubarb root 2 ozs., light magnesia 6 ozs., ginger 1 oz.)

Compound Rhubarb Pill, ... 1 to 2 pills, 5 grains in each.

(Contains rhubarb, aloes, myrrh, hard soap, oil of peppermint, and treacle.)

Uses.—The stimulating effect of rhubarb is experienced if a piece of the root be chewed in the mouth; it promotes the flow of saliva owing to the bitter principle it contains. It has a similar effect on the stomach, if taken in a small dose, acting, therefore, as a slight tonic to the stomach. Rhubarb contains a form of tannic acid, and, therefore, in small doses a slight astringent effect is produced. By larger doses the bowel movement is much increased, and a purgative action results, the flow of bile being also increased. After the contents of the bowel have thus been expelled, the tannic acid comes into play, and a binding effect is produced. Rhubarb is therefore, a very popular and useful remedy in cases of diarrhœa, due to the presence of some irritating material in the bowel, especially in children, for its first effect is to expel the irritant, and its later effect is to restrain the diarrhœa. For children it is commonly and rightly associated with magnesia for this purpose. The presence of piles is another condition in which rhubarb is useful, since it not only opens the bowels but exercises a tonic influence on the lining membrane of the bowel.

The doses named above are chiefly purgative doses. If tonic and astringent effects only are desired, less quantities, about half those named, would be employed.

Aloes is the dried juice of several varieties of the Aloe, belonging to the lily order of plants. There is the Socotrine aloes, derived from plants grown chiefly in Socotra and imported by way of Bombay, the Barbadoes aloes from the *Aloe vulgaris*, and Cape aloes.

Its preparations are as follows:—

	DOSE.
Barbadoes or other kind of Aloes in powder, ...	2 to 6 grains.
Tincture of Aloes (from Socotrine Aloe), ...	1 to 2 tea-spoonfuls.
Wine of Aloes ,, ,, ...	1 to 2 ,,
Compound Decoction of Socotrine Aloes, ...	2 tea-spoonfuls to 4 table-spoonfuls.
Extract of Aloes (from Socotrine Aloe), ...	1 to 3 grains.
Extract of Aloes (from Barbadoes Aloe), ...	½ to 2 ,,
Pill of Aloes (both kinds of Aloe), ...	1 to 2 pills of 5 grains each.
Pill of Aloes and Iron contains Barbadoes aloes, sulphate of iron, with compound cinnamon powder and confection of roses, ...	1 to 2 pills of 5 grains each.
Pill of Aloes and Myrrh contains Socotrine aloes, myrrh, saffron, and confection of roses, ...	1 to 2 pills of 5 grains each.
Pill of Aloes and Assafœtida contains Socotrine aloes, assafœtida, hard soap, and confection of roses, ...	1 to 2 pills of 5 grains each.
Aloin, ...	¼ to 2 grains.

Uses.—All varieties of aloes contain a bitter principle, **aloin**, which can be separated out in small colourless needle-shaped crystals, to which the effects of the aloes are due. Its chief effect is to stimulate the movements specially of the lower end of the large bowel. Influencing

mainly the termination of the bowel, its action is slow, so that it produces no effect for ten, fifteen, or even twenty-four hours after its administration, when it produces a large soft stool, with little griping, unless a large dose has been given, when pain and severe straining and even bleeding from the bowel may result. If it is given in large doses, the great irritation produced is not confined to the lower end of the bowel but affects neighbouring organs, and specially in women the womb. It stimulates also the secretion of the intestinal fluid, and it stimulates the liver, increasing the flow of bile. Indeed the presence of bile is necessary for its purgative action, and consequently in cases of illness, where there is absence of bile, if aloes is to be administered it is combined with purified ox-gall. These facts indicate very clearly the conditions in which aloes is a desirable purgative to employ, and also under what circumstances one ought to be chary of giving it.

If habitual constipation seems to be the result of weakness of the large bowel, the motions accumulating in the rectum, it is the proper purgative to use, *provided piles or other irritable condition does not exist.* It is improper to give it to women during pregnancy, from the risk of the irritation leading to abortion. But this very reason is one which indicates its usefulness in certain conditions of the womb associated with constipation. In absence of the monthly discharge it is given, combined with iron or myrrh, about the time the illness is expected, in order to stimulate its occurrence. One advantage of aloes in habitual constipation is that its use does not tend to make the constipation all the worse after its action. Increasing doses are not required as with most other purgatives, but rather the reverse. Owing to its slowness of action it is well to give aloes as a dinner pill, that is just before dinner, and it may then be expected to act next morning after breakfast. The most useful form of administration is aloin, given in pill in combination with other drugs to check any griping action. An excellent pill of this description is prepared by Schieffelin, of New York, of aloin, belladonna and strychnine, and to be had in the larger towns all over the world. They are very small and tasteless, but effective. The compound decoction is an excellent preparation, and useful in the constipation of children, when the motions are very hard, and accompanied by general digestive derangement.

Stronger Purgatives or Cathartics.

Cathartics, as already explained, are drugs which purge, but the term is usually applied to those which act more markedly than the simple purgatives already named. This they do by specially acting on the glands of the mucous membrane of the bowel, increasing the amount of fluid poured out, and producing watery stools. At the same time they also excite increased peristaltic movement of the bowel, and thus promote rapid expulsion of the contents. The chief of these are colocynth, scammony, and jalap.

Colocynth, as used in medicine, is the dried fruit, freed from rind and seed, the pulp, that is to say, of the *Citrullus colocynthis*, belonging to the cucumber order, and imported from Smyrna, Trieste, France, and Spain. Its dose and preparations are:—

Powdered Colocynth,	Dose, 2 to 8 grains.
Compound Extract of Colocynth contains colocynth, aloes, scammony, soap, and cardamoms,	,, 3 to 10 ,,
Compound Colocynth Pill (Gregory's Pill) contains colocynth, aloes, scammony, sulphate of potash, and oil of cloves,	,, 1 to 2 pills of 5 grains each.
Compound Colocynth and Henbane (or Hyoscyamus) **Pill** is the same as the compound colocynth pill, with the addition of a little extract of hyoscyamus to diminish pain and griping,	,, 1 to 2 ,, ,,

Uses.—Colocynth acts as a strong stimulant to the stomach and bowel, and after large doses the action becomes powerfully irritant, large quantities of fluid being poured into the bowel; in short, a catarrh is produced, just as irritation of the nostrils will cause a flow from them. At the same time the movement of the bowel is increased, so that griping pains are felt and the contents of the bowel are hurried on to the outlet. It does not matter whether the drug is taken by the mouth, injected up into the bowel, or whether the active principle it contains—colocynthin—is injected under the skin, the same results follow. The liver is also stimulated, and an increase in the outflow of bile excited. In large doses it acts as a drastic purgative, and would occasion in too large doses inflammatory symptoms. It is a useful medicine in obstinate constipation given with other drugs to aid or correct its action, such as in the compound pill. The compound pill with henbane is more agreeable, because the latter drug diminishes the

griping tendency. The purgative action is followed, however, by constipation, and this is a disadvantage. It is, nevertheless, a very useful pill for stout, full-blooded people, on any threat of excess of blood to the head, and in any case where quick relief to the liver and bowels is desired; but it ought not to be given to delicate persons, or any subject to bowel irritation.

Scammony is a plant belonging to the convolvulus order—*Convolvulus scammonia*—growing in Syria and Asia Minor. The dried root is used in medicine. From the fresh root a milky juice is obtained by cutting. This is mixed with juice scraped from the root, and is dried, forming the scammony of commerce. From this the pure resin of scammony is obtained by solution with spirit and precipitation in water.

Powdered Scammony,	Dose, 5 to 10 grains.
Resin of Scammony,	,, 3 to 8 ,,
Confection of Scammony,	,, 10 to 30 ,,
Compound Powder of Scammony, (Scammony powder 4 ozs., jalap 3 ozs., ginger 1 oz.)	,, 10 to 20 ,,
Scammony Mixture, (4 grains resin of scammony rubbed up with 2 ozs. fresh milk.)	,, ½ to 1 ounce for a child.
Compound Scammony Pill contains resin of scammony and of jalap, curd soap, and tincture of ginger,	,, 1 to 3 pills of 5 grains each.

Scammony is contained in the compound colocynth pills.

Uses.—This drug is a powerful purgative, owing to the presence of a substance called **jalapin**, promoting the expulsion of large watery stools, and increasing the flow of bile from the liver. It is not a reliable drug when given alone. It has no marked taste, and has, therefore, been used for children in the form of scammony mixture. It is used not only for constipation, but to expel tapeworm, but ought not to be used for delicate children.

Jalap is the dried tubercles from the root of a plant, the *Exogonium Purga*, found in the woods of the Mexican Andes. It is also cultivated in the Indian Nilgherry Mountains. The root is reduced to powder. From the root a resin is obtained by means of spirit. The chief preparations are as follows:—

	DOSE.
Powdered Jalap,	10 to 30 grains.
Resin of Jalap,	2 to 5 ,,
Tincture of Jalap,	½ to 2 tea-spoonfuls.
Compound Powder of Jalap contains powdered jalap 5 ozs., cream of tartar 9 ozs., ginger 1 oz.,	20 to 60 grains.

Uses.—Jalap and scammony resemble one another in containing an active principle, which is similar in both. That of jalap is called **convolvulin**, that of scammony **jalapin.** Jalap is less irritating and less likely to gripe. It increases slightly the flow of bile from the liver, but produces a most copious flow of watery fluid from the intestinal glands. It is because of this marked property of removing water that it is used in dropsies. The compound powder is the best for this purpose, owing to the presence of the cream of tartar, and when it is desired quickly to unload the liver, as in cases of congestion of the brain, it is combined with calomel, 5 grains of the latter and 15 or more of jalap, a grain or two of ginger being added to diminish pain. It will thus act in a couple of hours.

Drastic Purgatives.

Drastic purgatives are drugs which excite violent action of the bowels, producing a copious flow of fluid by irritation and increased activity of the bowel walls, the irritation passing into inflammatory action if the doses be large. Some of the drugs already considered act thus if given in excessive doses, such as colocynth, scammony, and jalap; and podophyllin, to be considered under drugs which promote the flow of bile, acts similarly if given freely enough. Such drugs are only employed either when it is necessary, even at the risk of great irritation of the bowels, to withdraw blood quickly from the head, as in threatened congestion or apoplexy, or when one seeks to remove dropsical fluid. They are too harsh remedies to be employed except by skilled persons, and then with great caution.

Elaterium is the most violent of drastic purgatives. It is the sediment from the juice of the ripe fruit of a plant belonging to the cucumber order, the *ecbalium* or *squirting cucumber.* Its dose is $\frac{1}{16}$th grain. A compound powder is made of 1 grain of elaterium and 9 of sugar of milk, of which the dose is ½ to 5 grains. The active principle of elaterium is **elaterin,** of which even $\frac{1}{40}$th grain is effectual.

Use.—Elaterium is employed to produce frequent watery motions, specially in cases of dropsy dependent upon heart-disease.

Croton-oil, Tiglium-oil, is another drastic purgative. It is an oil expressed from the seeds

of *Croton Tiglium*, of the natural order Euphorbiaceæ, found in some of the East Indian and Philippine Islands. It has been used from time immemorial in Hindostan as a purgative, though only introduced into Europe in 1820. Its dose is ½d to 1 drop mixed with olive oil, or made into a pill with bread crumbs. A liniment is made with oil of cajuput.

Uses.—Croton-oil is a powerful irritant, whether applied externally or taken internally. It is employed as a liniment to produce inflammation of the skin and the formation of pustules, as one might use a blister, for the sake of reducing inflammation in deeper structures. It used to be employed over joints in cases of inflammation, and on the chest in cases of lung affection, but is not now much employed. The pustules produced are slow to heal and leave unsightly scars. Internally, its irritating effects are experienced as a burning sensation in the throat and stomach, as sickness, perhaps, and speedy purging. Several motions follow the first, more liquid than it. It is seldom resorted to, even in obstinate constipation; but its speedy action—it purges in 1 or 2 hours—is sometimes sought in cases of apoplexy, shock, unconsciousness, where one desires to withdraw blood from the head, and where, because of its small dose, it can be easily administered even to an unconscious person. The dose is simply placed on the back of the tongue.

Gamboge, gum resin obtained from a tree indigenous to Siam, the *Garcinia Morella*. It is a drastic purgative, acting like colocynth, producing watery stools, but is never used alone, and seldom, indeed, at all. A compound pill contains aloes along with gamboge. It will expel worms from the intestine. Its dose is 1 to 4 grains.

Saline Purgatives.

To this class of purgative medicines belong the most commonly used medicines—Epsom salts, seidlitz powder, Rochelle salts, cream of tartar, &c. The chief cause of their purgative action seems to be dependent upon physical laws. On p. 134 the physical process called osmosis has been described. If two fluids containing some salts in solution be separated from one another by an organic membrane, an interchange will occur between the two fluids through the membrane until the fluid on both sides of the membrane come to be alike in the quantities of salts they have in solution. If, for example, on one side of the membrane is water containing much common salt in solution and the fluid on the other side contains less, water will pass through the membrane to dilute the strong solution. If a liquid be swallowed, then in the stomach there is a state of things such as has been suggested. In the stomach is a liquid; flowing in the blood-vessels of the walls of the stomach is another liquid, the blood; these two fluids are separated by an animal membrane, the walls of the blood-vessels; if the two fluids differ from one another in density then an exchange will occur between the blood and the contents of the stomach. Suppose pure spring water has been drunk. It will speedily pass into the blood, diluting it, and the water will then be separated out by the kidney. If the water contain a large quantity of dissolved salts, then water will pass from the blood into the stomach to dilute it, and the bowel will contain a large quantity of fluid material. This is at least a large portion of the mode of action of these saline substances. Doubtless they not only drain water from the blood by this physical process, but also excite the glands, and to some extent increase the movement of the bowel. Sometimes, however, the saline medicine produces little increase of the wave-like movement of the bowel. This explains what sometimes occurs after taking a seidlitz powder. The person feels oppressed with the quantity drank, and the feeling of loaded bowels increases rather than diminishes, but no purging occurs. The powder has acted as explained, and a large quantity of liquid accumulates in the bowel, but for want of stimulus to the wave-like motion of the bowel—peristaltic movement—the fluid is not swept onward. It is gradually reabsorbed and passed back into the blood, and no motion results. To avoid this it is well to combine some simple purgative with the saline draught. Thus a purgative pill is taken at night and a seidlitz powder in the morning; that is to say, when it is about time for the pill to produce increased action of the bowel the seidlitz powder causes a flow of fluid to the bowel, which is then swept onward. The old black draught—syrup of senna and a solution of Epsom salts—is an illustration of the same thing.

Epsom Salts are the sulphate of magnesia. They produce watery stools, but excite the movement of the bowel very little, and may be usefully combined with senna or cascara sagrada (see p. 858). To secure by a single dose purgative action, ½ to 1½ ounces are needful; if taken in repeated doses, 1 to 2 tea-spoonfuls are sufficient each time. About a third of a tea-spoonful in water will act upon the kidneys

rather than the bowels if the skin be cool, but will help to cause sweating if the skin be kept warm. A full dose is very useful in feverish conditions, and repeated small doses are advised for biliousness. The early morning is the best time for taking this as well as other saline medicines.

Cream of Tartar, the acid tartrate of potash, has already been mentioned in considering the potash salts (p. 818). If given in doses of from 2 to 8 tea-spoonfuls it acts as a purgative, copious watery stools resulting; if given in doses of from ⅓ to 1 tea-spoonful it acts upon the kidney, increasing the quantity of urine; or, if the body be kept warm, upon the skin, increasing the sweat. Thus an excellent cooling drink—the imperial drink—is made with 1 or 1½ tea-spoonful of cream of tartar, a little sugar, 1 pint of boiling water, and half the peel of a fresh lemon. When used as a purgative it is in combination with jalap or scammony, and usually to remove dropsical fluid.

The tartrate of potash (dose: ¼ to ½ oz.) and the sulphate of potash (dose: 15 to 60 grains) are also used as purgatives, and the general remarks already made at the head of this paragraph apply to them.

Rochelle Salts are the tartrate of soda and potash or tartarated soda. They act like other saline purgatives, but excite the peristaltic movement of the bowel more than Epsom salts. In ¼ to ½ ounce doses this is their effect; in small doses, ½ to 1 tea-spoonful, they increase the flow of water from the kidney.

Seidlitz Powder is a mixture of Rochelle salts and bicarbonate of soda in fine powder, 120 grains of the former and 40 grains of the latter. It is employed for such purposes as have been mentioned in speaking of Epsom salts. It is commonly employed as an effervescing drink. To produce the effervescence the addition of tartaric acid in fine powder to the seidlitz powder, when dissolved in water, is necessary. The seidlitz powders of the shops, therefore, contain the seidlitz mixture in one paper, and in a second paper 37 grains of powdered tartaric acid. The double-strong seidlitz powder contains, in the paper holding the seidlitz mixture, an additional quantity of Rochelle salts to the amount of 160 grains.

Glauber's Salt is the sulphate of soda, of which the dose is from ¼ to 1 oz. It purges by increasing the flow of watery fluid, but also excites the movements of the stomach and bowels. It is a constituent of Carlsbad, Friedrichshall, Hunyadi Janos, and Bilin mineral waters. It is specially useful in cases of torpid liver and habitual constipation, and in ulceration and dilatation of the stomach, and should be taken in the morning. It is best taken in the form of the crystallized Carlsbad salts, of which ⅓ tea-spoonful should be taken in a large tumblerful of warm water immediately on rising.

Phosphate of Soda is a useful purgative for children, as it has little taste and acts gently. It is given in milk or food to the amount of from 3 to 10 grains, and its use is indicated by the occurrence of green or white stools. For adults the dose is ¼ to 1 ounce.

The Fruit Salts which, on the initiation of Eno, have become so widely used, are combinations of Epsom salts, bicarbonate of soda, tartaric acid, white sugar, or similar preparations. As mild purgatives they are very useful, and may be used as cooling and refreshing drinks.

Purgatives which Increase the Flow of Bile.

It has been noted regarding several of the drugs already mentioned that they stimulate the liver and promote the secretion of bile, notably rhubarb, aloes, colocynth, scammony, jalap. Phosphate of soda, Glauber's salt, Rochelle salts, and other substances have also a similar, though less marked, effect. In the meantime, however, we need to notice here only a few purgative drugs which markedly affect the outpour of bile from the liver, leaving to another place (p. 874) to notice other medicines which stimulate the liver without acting as purgatives. The drugs to be noted are podophyllin, euonymin, and iridin, &c. Calomel and other mercurial preparations, such as grey powder, blue pill, &c., have held long a high reputation for acting on the liver. It would appear that they do not stimulate the liver nearly to such an extent as podophyllin and other drugs. What they do accomplish, however, is a thorough sweeping of the bowel of its contents. How this acts in relieving the liver can be briefly explained. When the bile is poured into the bowel, just at the commencement of its course, it is mixed with the food, aiding its digestion and absorption into the circulation. Much of the bile is reabsorbed along with the nutritive portion of the food, and is passed back into the liver, and only a fraction of it is ultimately expelled from the bowel in the motion. The slower the movement of the food along the bowel the greater will be the amount of reabsorption, and the

less bile will be expelled from the body. On the other hand, anything which quickens the intestinal movement, anything which hurries the food along the bowel to the outlet, will secure the expulsion of a greater quantity of bile from the body by permitting less time for its reabsorption. It is in virtue of this action that calomel and other drugs have gained their repute for biliousness, relieving the liver, and so on. They so stimulate the bowel movements that the bile poured into the bowel is hurried along with the food, and appears in the loose motions, no time being allowed for its being picked up and passed back to the liver. Thus the bowels are cleared out, the liver is prevented receiving back much material it otherwise would have had returned to it, water is drained from blood-vessels supplying the liver, and that organ is at once greatly relieved and also stimulated, because the liver cells are excited to produce more bile to make up for that which has been lost by the action of the medicine. This explanation will also make it clear how prolonged constipation occasions such a feeling of weight, languor, drowsiness, headache, and produces a sallow dirty complexion. People say this is biliousness, but the biliousness is the effect, not the cause. The sluggish state of the bowel permits the motions to remain long before expulsion, allows time for reabsorption of much of the bile, and the liver is oppressed, not because it itself is to blame, but because an outlet is denied to the bile it produces, which is always being returned to it. Under these circumstances, any medicine which will open the bowel and will quickly sweep out its contents will afford immediate and great relief, even although the liver is only indirectly and but slightly stimulated. To this extent, then, every medicine which acts as a brisk purgative will stimulate or at least relieve the liver, by causing a greater quantity of bile than usual to be expelled altogether from the body. The drugs we have now to consider act directly upon the liver cells, creating an increased *production* of bile by their stimulating effects upon the liver substance, while they also excite the bowel to its speedy expulsion.

Podophyllum is the dried root-stock and rootlets of the *Podophyllum peltatum*, or American **May Apple**, called also **Mandrake** in the United States, where it grows plentifully in rich woodlands. It belongs to the order Berberidaceæ. From this a resin is obtained by means of rectified spirit, called resin of podophyllum or podophyllin.

	DOSE
Powdered Podophyllum, ...	10 to 20 grains.
Podophyllin (the resin), ...	½ to 1 grain.
Tincture of Podophyllin, ...	15 to 60 drops.

Uses.—Podophyllin is a powerful purgative, increasing the secretion from the bowel and from the liver, and it thus acts even when injected into the blood. Thus also the resin applied to an ulcer or open wound will produce similar effects along with sickness. It is irritating even to the sound skin, and very irritating to the delicate membrane of eyes, nose, throat, &c., as experienced by workmen engaged in pounding the root. It is a powerful stimulant of the liver, and is particularly useful in the treatment of torpor of the liver, such as is so frequent in persons of a full habit, who live well, and take insufficient exercise, and in cases of bilious headache. Its action upon the bowel, though marked, is, in moderate doses, not very rapid. Its dose can be so regulated that only a single gentle but full motion occurs, but if larger doses be given it purges several times, the stools being very liquid. It does not tend, after moving the bowels, to induce subsequent constipation, and may therefore be used regularly for a long time for habitual constipation. Its tendency to gripe makes it desirable to combine its action with that of other drugs. A good form of administration is—

Resin of Podophyllin, ...	⅛ grain.
Extract of Belladonna, ...	⅛ ,,
Extract of Hyoscyamus, ...	1 ,,
Extract of Nux vomica, ...	¼ ,,

Make into 1 pill.

One of these pills may be taken daily either at bed-time or just on rising, and before any food has been taken. It may be employed for children suffering from habitual constipation, and for them a solution of ¾ grain of podophyllin in 100 drops of rectified spirit is recommended. Of this solution a child may receive from 2 to 10 drops in a tea-spoonful of syrup.

Euonymin is a comparatively recent addition to the list of drugs which stimulate the secretion of bile, while at the same time acting as a purgative like rhubarb or colocynth. It is the active principle of a bark, the bark of the *Euonymus atropurpureus*, belonging to the natural order Celastraceæ, a shrub 6 to 10 or even 14 feet high, found in shady woods of the northern and middle section of the United States of America, east of the Mississippi. It is also called the Wahoo, spindle-tree, or burning bush. The active principle euonymin is

obtained from a concentrated tincture of the bark by precipitating with water.

Euonymin,	Dose, ½ to 5 grains.	
Best given in pill with 1 grain extract of hyoscyamus.		
Tincture of Euonymus (made with 1 oz. of euonymus bark and 4 ozs. rectified spirit),	,,	10 to 40 drops.
Extract of Euonymus,	,,	2 to 5 grains.

Euonymin is given in the same circumstances which indicate the need of podophyllin—bilious headache, sluggish liver, constipation. A decoction may be prepared from the bark itself, 1 oz. of bark to 1 pint hot water, infused for half an hour and strained; of this a wine-glassful is a dose. It is advised to take euonymin at bedtime, and to take a saline purge in the morning, sulphate of soda (see p. 863) being the best.

Iridin is a powdered extractive derived from the rootlets of the blue flag or water-flag, *Iris versicolor*, "common in wet and swampy meadows from Canada southward to Florida, and westward to Minnesota and Arkansas." In the United States the following preparations are used:—

	DOSE.
Extract of Iris,	1 to 5 grains.
Fluid Extract of Iris,	5 to 60 drops.
Iridin,	1 to 5 grains.

It is used in the same circumstances as podophyllin and euonymin, and has similar effects. It may be given in pill like euonymin, with hyoscyamus to prevent griping.

Hydrastis.—Golden Seal, Yellow Root, Yellow Puccoon, Orange Root, Indian Dye, Indian Turmeric, are all names for the same plant, *Hydrastis canadensis*, belonging to the Ranunculus order, indigenous to Canada and the United States. It is used in the following forms:—

	DOSE.
Powdered Root,	10 to 30 grains.
Hydrastin,	½ to 5 grains in pill.
Tincture of Hydrastis,	30 to 60 drops.
Fluid Extract of Hydrastis,	1 to 2 tea-spoonfuls.

Use.—This drug is said not only to be a valuable remedy for habitual constipation dependent upon inaction of the liver, but to be also a good tonic to the stomach, and one of the best remedies for the stomach catarrh consequent upon chronic drinking, and probably the best substitute for alcoholic stimulants when their use has to be abandoned. It is also said to be very useful as a lotion in inflammation of the eyelids, as an injection in discharges from the ear, the genital passages, &c. For such purposes two tea-spoonfuls of the tincture to a pint of water may be employed.

Leptandrin, an active principle obtained from the rootlets of *Leptandra virginica* or Culver's-root, Culver's Physic, Black-root, **Baptisin,** derived from the roots of the *Baptisia tinctoria* or Wild Indigo, **Juglandin,** the powdered extractive from the inner bark of the root of *Juglans cinerea*, or Butternut, **Phytolaccin,** the powdered extractive obtained from *Phytolacca decandra*, or Poke-root—all of the plants being indigenous to the United States—are substances which have effects similar to podophyllin in stimulating the liver and bowels. Their doses are as follows:—

	DOSE.
Leptandrin,	½ to 2 grains in pill.
Fluid Extract of Leptandra,	30 to 60 drops.
Juglandin,	2 to 5 grains in pill.
Extract of Juglans,	20 to 30 grains.
Phytolaccin,	1 to 5 grains in pill.

It may be noted regarding juglandin that allied plants to the *Juglans cinerea*, notably the English walnut (*Juglans regia*) and the black walnut, have also been used for medicinal purposes, decoctions or poultices made from the leaves being popularly used for the treatment of sores, and ulcers of all parts, and discharges of all kinds. The decoction, tincture, and juice of the leaves of Phytolacca have been used for similar purposes, and for various skin eruptions, such as ringworm, itch, and mange in dogs. Phytolacca has also a popular reputation for relieving the pains of rheumatism and procuring sleep. It is used in these cases as a tincture of the root or the berries, or a decoction of the root.

Remarks on the Use of Purgatives.—Opening medicines must never be given without due regard to the age and condition of the person. The young and the aged, as well as those of all ages and both sexes who are delicate, or reduced by disease, ought not to have strong opening medicines. The mildest of laxatives ought to be employed, and that after an endeavour has been made rather to regulate the bowels by proper diet. The simplest aperient is castor-oil, and sulphur and senna are also mild in action. In many such cases an injection is preferable to medicine by the mouth. The saline purgatives may be given, but they ought to be warmed, and probably the best will be found in one of the mineral waters, Hunyadi Janos, Carlsbad, or Friedrichshall. Then again caution ought to be displayed in administering purgative medicines to any suffering from irritable or ulcerated conditions of the bowel, or from piles

or fissure of the anus, or in cases of pregnancy, or during the monthly illness. Again, it must be remembered that the frequent use of purgatives rather confirms than diminishes a tendency to constipation, and a drug ought, if possible, to be selected which has not this disadvantage. This is the objection to the use of the commonly employed pills, colocynth, &c. It has been pointed out that this disadvantage is got rid of by the use of cascara sagrada, and is not a feature of aloes or podophyllin. Then an endeavour to note the chief feature of the constipation will aid in selecting the drug. If large, hard, dry motions are passed, the indication is that the remains of the food pass too slowly along the bowel, so that too much fluid is removed from them. This aloes would probably aid, or podophyllin, or rhubarb, or senna in the form of compound liquorice powder, or a morning draught of saline medicine. Very dark coloured stools point to the need of a stimulant to the liver, such as podophyllin. When a thorough clearing out of the bowel is desired to relieve the overloaded system, or as a preliminary to the commencement of some medicinal treatment, the best means is a colocynth and hyoscyamus pill at night, and a double strong seidlitz powder in the morning. This also is suitable in the beginning of any inflammatory illness, of lung for example, but not when the bowel itself is affected. Constipation, along with dulness of spirits, headache, and sallow complexion indicates the need of a purgative which shall also stimulate the liver, such as podophyllin. The drastic purgatives ought not to be employed except when ordered by a medical man.

Remedies for Diarrhœa.

Looseness of the bowels may be due to several causes. It may arise from an excessive irritability of the bowel, which causes its peristaltic movement to be increased by the very smallest stimulus. An illustration of this is given by the kind of diarrhœa which threatens the person as soon as he takes food, or a short time after. The entrance of food so excites the whole bowel that its contents are hurried along with unusual rapidity. The remedies applicable to such a case are those which diminish irritability of the bowel, which soothe the bowel. Of these the most employed are **opium** in some form (see section on Drugs which Act on the Nervous System), **belladonna** (see also section just named), and **hyoscyamus** (also considered in the section noted). A single drop, or three drops, of laudanum taken before sitting down to a meal will frequently check this irritability.

Again, diarrhœa is often due to the presence of irritating material in the food, and the obvious remedy for this is to expel it from the bowel as quickly as possible, when the diarrhœa will cease. Thus, castor-oil, or rhubarb, is often the best remedy, the clearing out of the bowel being followed by an astringent action. A few drops of laudanum (4 or thereby) may be added to the oil or rhubarb. Indeed at the very outset of diarrhœa this treatment should in every case be adopted. Then one starts with the knowledge that the bowel is clear, and, if needful, other medicine can then be given.

Excessive acidity of the food is often a cause of diarrhœa, the high degree of acidity acting as an irritant. The bicarbonate of **soda**, or **potash**, **magnesia** carbonate, or some preparation of **lime** (see p. 843), will be the appropriate remedy in such a case. In children diarrhœa is very often due to the milk curdling in too large pieces in the stomach. These pieces are annoying to the bowel, as they are too large to be easily digested, and as they pass along the bowel they excite it more and more. The addition to the milk of a pinch of soda, a tea-spoonful or two of fluid magnesia, or a tea-spoonful of lime water, will prevent the too rapid curdling of the milk by the acid juice of the stomach, smaller curds will be formed, easy of digestion, and the diarrhœa will cease. In looseness of this kind the presence of small pieces of white curd in the stools sufficiently shows the nature of the complaint.

These methods of checking diarrhœa are indirect, the cause of the irritation of the bowel is removed, and the flow ceases. But there is a set of drugs which act upon the blood-vessels of the bowel, causing them to contract, diminishing the flow of blood through the mucous membrane of the bowel, and thus diminishing the production of intestinal fluid. In short, the opposite action is sought to that described under purgatives, by which one seeks to *increase* the flow of intestinal fluids. This astringent effect on the blood-vessels of the bowel is accomplished by **acids**, the acids named on p. 841. The **acetate of lead** is also valuable in this way (see p. 836).

There is next a group of substances which act upon the whole tissue of the bowel exposed to their influence, constringing it, and so checking any discharge, whether it be mucus or blood. The chief of these substances are catechu, kino, krameria or rhatany, oak-bark, and they are

dependent for their constringing action upon the tannic acid or some variety of it which they contain. The action of tannic acid and gallic acid we shall therefore first consider.

Galls are excrescences on a variety of oak found in Asia Minor, *Quercus infectoria*, due to the punctures and deposit of eggs of an insect, *Cynips gallæ tinctoriæ*. The irritation causes a swelling to occur which surrounds the egg, and within which the insect develops. When the nuts are broken a central cavity is seen in which the insect may be found, or it may have already escaped, in which case a canal will be found bored to the surface. The preparations of galls are:—

Tincture of Galls,......... Dose, ½ to 2 tea-spoonfuls.
Gall Ointment.
Gall and Opium Ointment.

The action of galls is practically the same as that of tannic acid, obtained from it. It is in the form of the gall or gall and opium ointment it is chiefly employed. This is used as a local astringent to the bowel in cases of piles, being simply applied to the part.

Tannic Acid is extracted from powdered galls with ether. It has a very strong astringent taste, and is very easily dissolved in water.

Tannic Acid,............................ Dose, 2 to 10 grains.
Glycerine of Tannic Acid contains 1 of tannin to 5 glycerine, dissolved by aid of heat.
Suppositories of Tannic Acid.
Lozenges of Tannic Acid,........ Dose, 1 to 6 lozenges. (½ grain of acid in each—the American lozenges contain 1 grain in each.)
Styptic Colloid (20 of tannic acid, 5 of alcohol, 20 of ether, 55 of collodion).

Uses.—Tannin coagulates albumin, and, applied to broken skin, causes it to contract by coagulating the fluids of the tissue. The blood-vessels of the part are reduced in size by the contraction of the surrounding tissues, and thus bleeding is arrested, as well as by the clotting of any blood by the influence of the tannin. In contact with the lining membrane of the mouth, gullet, stomach, and bowels, it produces dryness by coagulating the mucus, and the constringing effect produces a sensation of roughness and stiffness, diminishing the flow of blood along the vessels, and in this way, as well as by a direct action, diminishing secretion. These effects indicate in how many ways tannin is useful. It is employed to stop bleeding and discharges in all situations, from nose, throat, skin, bowels, womb, &c. For these purposes the glycerine compound is very well suited. The suppositories are useful in piles and other conditions of the lower end of the bowel. It is given also to arrest bleeding in organs besides the stomach and bowels. Its effect in checking bleeding in the stomach and bowels is readily understood, but it is also believed to check bleeding in other organs, such as the lungs, though given by the mouth. It reaches the blood and distant organs as gallic acid. For such bleeding, therefore, the use of gallic acid itself is to be preferred, since the local effect of tannic acid is not desired. It is seldom given for diarrhœa, and only in extreme cases.

Gallic Acid is prepared from galls by allowing a paste formed of pounded galls to ferment, gallic acid being derived from the splitting up of tannic acid.

Gallic Acid,................ Dose, 2 to 10 grains.
A glycerine and ointment are prepared.

Gallic acid is chiefly used in cases of bleeding from organs which can be reached only through the blood, such as the lungs and kidneys. In bleeding from the lungs, it is given in doses of 10 grains every two hours.

Catechu, as employed in medicine, is an extract of the leaves and young shoots of *Uncaria Gambier*, a shrubby climber indigenous to countries about the Straits of Malacca, and extensively cultivated near Singapore. Its preparations are:—

	DOSE.
Powdered Catechu,.........	10 to 30 grains.
Tincture of Catechu,.....	½ to 2 tea-spoonfuls.
Infusion of Catechu, ...	2 to 4 table-spoonfuls.

(Coarse powder of catechu 160 grains, bruised cinnamon 30 grains, boiling water 10 ounces; infuse half an hour and strain.)

Compound Powder of Catechu (contains catechu 4, kino 2, rhatany 2, cinnamon 1, nutmeg 1), .	Dose, 15 to 30 grains.
Lozenges of Catechu,...........	,, 1 to 3 lozenges.

Uses.—Catechu is used because of the effect of the tannic acid it contains. It is used as an astringent for the mouth in the case of soft bleeding gums, and for the throat in relaxed conditions, and for hoarseness. In these cases the lozenges are useful, or the infusion may be used as a gargle. It is employed as a lotion for bleeding from the nose, and as an application to cracked nipples. The tincture or infusion is very useful for diarrhœa in children, and is usually employed for adults in combination with a little tincture of opium and chalk mixture.

Black Catechu, Terra Japonica, or Cutch, an extract prepared from the wood of *Acacia Catechu* is to be distinguished from the above, which is pale catechu. Its dose is 5 to 15

grains, and in America a compound tincture and lozenges are made of it.

Kino is the juice obtained from incisions made in the trunk of the kino tree, indigenous to India and Ceylon, called buja in Bengal, the technical name being *Pterocarpus Marsupium.* It is imported in the dried state from Malabar. It contains a species of tannin from which it derives its most important qualities. Its preparations are:—

	DOSE.
Powdered Kino,.....................	10 to 30 grains.
Compound Powder of Kino (Powdered kino 15, opium 1, powdered cinnamon 4),..	5 to 15 ,,
Tincture of Kino,..................	½ to 2 tea-spoonfuls.

It is useful as a gargle for relaxed throats, the tincture being added to water, and it is employed in diarrhœa, and in the stomach disorder called pyrosis or water-brash. It is milder in action than catechu.

Rhatany is the dried root of *Krameria triandra,* a low shrub native to Bolivia and Peru.

	DOSE.
Powdered Rhatany,............	20 to 60 grains.
Extract of Rhatany,...........	5 to 20 ,,
Infusion of Rhatany (1 oz. in 20 boiling water, infused 1 hour and strained),	2 to 4 table-spoonfuls.
Tincture of Rhatany,..........	1 to 2 tea-spoonfuls.

Uses.—Rhatany is an astringent like the others, and its astringent effects are brought to play upon external affections, such as ulcers, fissure of the anus, cracked nipples, &c., as well as upon diarrhœa and other internal disorder. It is used as an injection in dysentery and for uterine complaints, also as an injection.

Red Gum is an exudation from the bark of *Eucalyptus rostrata,* the red gum-tree, and imported from Australia. Its preparations are:—

	DOSE.
Decoction of Red Gum,.........	2 to 4 tea-spoonfuls.
Liquid Extract of Red Gum,...	30 to 60 drops.
Tincture of Red Gum, ...	20 to 40 ,,
Syrup of Red Gum,................	30 to 60 ,,
Red Gum Lozenge,...Each lozenge contains 1 grain.	

Use.—Red gum is an excellent remedy for various kinds of relaxed mucous membrane. As the lozenge it is excellent for hoarseness and relaxed throat. Mixed with an equal quantity of starch in fine powder it may be blown into the throat. A tea-spoonful of tincture to 7 of water makes an excellent gargle, and a table-spoonful of the liquid extract to a pint of water forms an astringent injection for the bowels or genital passages, or to inject into the nostril, either to stop mucous discharge or bleeding. The tincture or liquid extract or decoction may be used for diarrhœa or bleeding from the bowel, or dysentery. In these latter cases it is often given with liquid extract of bael fruit.

Bael Fruit is the dried half-ripe fruit of *Aegle Marmelos,* the Indian Bael, or Bengal Quince, belonging to the orange order. The fruit resembles an orange of large size and the juice is gummy and pleasant flavoured. Its preparation is:—

Liquid Extract of Bael,.... Dose, 1 to 2 tea-spoonfuls.

It is extensively used in India, because of its astringent qualities, in the treatment of bowel complaints. In chronic diarrhœa following typhoid fever it has been found singularly efficient, and it is sometimes applied as a wash to the eyes when inflamed. It is frequently given in combination with liquid extract of red gum.

Logwood is sometimes used as an astringent in diarrhœa and dysentery. It is the sliced heart-wood of *Hœmatoxylon campechianum,* native to the shores of the Gulf of Campeachy, and naturalized in many of the West Indian Islands. A decoction and extract are prepared, the dose of the former being 1 to 2 ozs., and of the latter 10 to 35 grains. It colours the urine of those taking it pink. It is a mild astringent, quite suitable for use in checking diarrhœa of infants, to whom it may be given by the mouth or as an injection.

Oak and Elm Bark also contain tannic acid, and decoctions might be used as astringents like catechu, kino, &c. The decoction of oak bark is made of a strength of 1 of the bark to 15 of water, and the dose is 1 to 2 ounces; that of elm bark is 1 in 8, and the dose is 2 to 4 fluid ounces.

Alum, a compound of ammonia and alumina with sulphuric acid, the sulphate of ammonia and alumina, is a very strong astringent. Its preparations are:—

Powdered Alum, ...	Dose, 10 to 20 grains.
Dried or Burnt Alum,...	Externally for proud flesh, &c.
Iron Alum, ...	Dose, 5 to 10 grains.

Use.—Alum has a marked constringing action. The burnt alum, when applied to any raw surface, sears the surface, and is therefore used for "proud flesh," and for foul ulcers. When a weak solution of alum is taken into the mouth, its constringing action on the lining membrane is at once perceived; when it is absorbed into the blood and conveyed to the various tissues it appears to exert a similar effect upon them also. It is, however, used

chiefly for its local effect, and not much for effects after absorption into the circulation, though it is sometimes employed for arresting bleeding, as from the lungs, and discharges from various organs. Its local effect is obtained by using it in the form of gargles and washes. Thus a gargle of 60 grains alum, 2 tea-spoonfuls of honey, and 6 ounces of water is very useful for relaxed and inflamed throat, or soft spongy gums; another gargle of 60 grains of alum, ½ tea-spoonful of tincture of myrrh, and 4 ounces of water is useful under similar conditions and in ulcerated conditions of the mouth and throat. For checking bleeding from the mouth, nose, gums, anus, or from leech bites, it may be applied as a dusting powder, or in strong solution (60 grains to the ounce or stronger), upon a sponge or lint. For injection, alum may be used of a strength of 1 tea-spoonful and upwards of the powder to a pint of water, and the iron alum is a valuable preparation for this purpose. These are commonly used injections in discharges from the genital organs in women. A solution of from 1 to 3 grains in an ounce of water is good for inflammation of the eyelids accompanied by matter. Alum may be administered internally in the dose stated above, given in water or syrup or dissolved in white of egg solution, or in the form of alum whey. **Alum whey** is prepared by boiling 120 grains of alum in 1 pint of milk and straining. An ounce of this might be taken at a time. It may be thus administered for bleeding from the kidneys or bowels or for diarrhœa. The diarrhœa of typhoid fever is said to be better treated by alum than by any other astringent except acetate of lead; and in chronic dysentery it is valuable when used occasionally. Alum acts, however, as a purgative if given in large doses (60 grains), doubtless because of its irritant effects, and this quantity, or double, given in treacle or syrup acts as an emetic, draughts of warm water promoting the sickness once retching has commenced.

Iron Preparations are useful as intestinal astringents in diarrhœa and bleeding (see p. 817).

Copper Preparations are also sometimes used for diarrhœa, because of their astringent action on the bowel. The chief compound of copper used as a drug is:—

Sulphate of Copper, ... Dose, ½ to 2 grains.

Verdigris is a subacetate of copper, but is not used in medicine.

Uses.—Copper is very frequently used because of its astringent effects when applied directly to ulcers, wounds, &c., in the form of **blue-stone.** When applied in mass to the broken skin, or sprinkled on as a fine dust, it acts as a caustic, and is used for warts, proud flesh, unhealthy ulcers, and poisoned wounds. It is, however, far too frequently employed in domestic surgery. The "proud flesh," which sprouts from a healing wound, is to the uneducated eye a very undesirable thing, to be "burnt off" time and again, but to the surgeon it is the thing to be desired, as by it the wound is healed. If it becomes "exuberant," as the phrase is, he diminishes that tendency by the well-regulated pressure of a bandage, but probably the skilful surgeon almost never takes a piece of blue-stone between his fingers, unless it is to throw it away, as one has expressed it. When used in solution of 3 or 4 grains to the ounce of water it acts as a stimulant. A solution of 2 to 5 grains to the ounce is occasionally used as an injection, but not frequently, and specially in falling of the bowel and excessive secretion in that neighbourhood. Given in small doses internally, it acts as a tonic and astringent to the stomach and bowels in diarrhœa and dysentery. For such purposes it is often combined with opium, ¼ grain sulphate of copper, ¼ grain gum opium, made into a pill with confection of roses, and given occasionally. Dysentery is often benefited by an injection into the bowel of a pint of tepid water containing 10 to 20 grains of sulphate of copper in solution. Copper in small doses in pill has also been administered as a tonic to the nervous system in St. Vitus' dance and epilepsy. In large doses (2 to 10 grains of the powdered sulphate mixed with powdered sugar or dissolved in 2 ounces of water) copper is very useful as an emetic, especially in cases of laudanum or other narcotic poison. It does not produce nausea or depression and it acts rapidly. It is also used as an emetic in croup and bronchitis to expel material from the air-passages, the absence of depression being in such cases a great advantage. Poisoning by copper is not common, because of its emetic action, unless very large doses, leading to ulceration of bowel, have been taken. It is also employed as an antidote to phosphorus poisoning, 3 grains of the sulphate being given in water every few minutes, till vomiting occurs, after which a seidlitz powder should be administered.

Zinc is employed in cases almost identical with those for which copper may be used, but is much more freely used than the latter. Its preparations in common use are:—

	DOSE.	
Sulphate of Zinc,......	1 to 3 grains	as tonic.
	10 to 30 ,,	as emetic.
Oxide of Zinc,.........	2 to 10 ,,	in pill.
Acetate of Zinc, ...	1 to 2 ,,	as tonic.
	10 to 20 ,,	as emetic.
Valerianate of Zinc, ...	1 to 3 ,,	
Phosphide of Zinc,......	$\frac{1}{10}$ to $\frac{1}{3}$,,	

Zinc Ointment (80 grains of oxide of zinc to 1 oz. of benzoated lard).

Oleate of Zinc.

Chloride of Zinc, ... For external application only.

Uses.—Like copper, zinc when used in strength acts locally as a caustic, and when in weaker solution acts as an astringent and tonic. It is of very wide application in the form of lotion and ointment for wounds, sores, ulcers, and inflamed surfaces generally. The chloride of zinc is highly caustic, and is used in solid sticks to destroy tumours, and in strong solution to wash over foul ulcers. In solutions of 2 grains to the ounce it is a valuable tonic and stimulant to sores and wounds of various kinds. The sulphate of zinc in solutions of 1 and 2 grains to the ounce of water is used to bathe wounds, to bathe inflamed and mattering eyelids, and for injections to limit discharges from the womb, &c. It is also a soothing and cooling application to itching diseases of the skin, specially eczema. Zinc ointment is a soothing and healing ointment, and the more recent oleate of zinc is a better application, mixed with lard or vaseline to the amount of 1 part of the former to 3 of the latter. Oxide of zinc dusted very lightly in very fine powder is a soothing dusting powder for surfaces inflamed by rubbing against one another, such as frequently occurs in children. Taken internally, zinc acts as an astringent and tonic in small doses, and an irritant and emetic in large doses. The oxide is given occasionally for diarrhœa, and has been administered in chronic cases of diarrhœa to children with successful results. The sulphate may be given for the same purpose. The oxide, valerianate, and phosphide of zinc are used in nervous diseases, especially those of a convulsive type, such as St. Vitus' dance (chorea), epilepsy, whooping-cough. Two-grain doses three times a day may be given in pill, of the oxide and valerianate, and $\frac{1}{3}$ of a grain of the phosphide. The oxide of zinc is most frequently used to control excessive sweating, and in particular, the night sweats of consumption, for which it may be given in pill of 1 or 2 grains at bed-time. The sulphate and acetate of zinc are most valuable emetics (see p. 851).

Silver Salts have also astringent and tonic properties. The salts chiefly used are:—

Nitrate of Silver,............	Dose,	$\frac{1}{6}$ to $\frac{1}{3}$ grain.
Oxide of Silver,...............	,,	$\frac{1}{2}$ to 2 grains.

Uses.—Like copper and zinc, silver salts are used externally rather than internally. The solid stick of fused nitrate of silver, commonly called "lunar caustic," is applied to produce superficial destruction of tissue, in the case of chronic ulcers, the result being to stimulate healthy action. Solutions of varying strength (1 to 10 grains to the ounce) are used for like purposes, sore nipples, &c. The solid stick is applied to warts, and a stick is prepared with 1 part of silver nitrate to 2 parts of nitrate of potassium for similar uses, and called **mitigated nitrate of silver.** Internally, nitrate and oxide of silver are used for their tonic and astringent properties in chronic ulceration and inflammation of the stomach, and in chronic diarrhœa and dysentery. For this $\frac{1}{4}$ grain is the dose in pill with bread crumb. In epilepsy and St. Vitus' dance, it is given in similar doses, thrice daily, as a nerve tonic. In all these cases the use of the drug must not be continued beyond 3 or 4 weeks, because of the risk of staining the skin of the whole body brown, a staining which cannot afterwards be removed. If a piece of lunar caustic has been swallowed by accident, a draught of salt and water should be given immediately along with an emetic, for salt forms with it an insoluble substance, chloride of silver. The salt should be given along with gruel drinks or gummy drinks to protect the gullet, when the silver is vomited up.

Remarks on the Use of Remedies for Diarrhœa.—It is a mistake to suppose that on the occurrence of diarrhœa, the immediate thing to be desired is to check the discharge. In a very large number of instances, the looseness is the result of some article of food or drink which is irritating the bowel-walls, and the flux or discharge is the effort of nature to sweep it away. In the first instance, therefore, this effort should be aided, and aided so thoroughly that one may be certain all irritating substances have been swept out. If the diarrhœa still continues, as it may well do, if the irritation has been severe, then one can with confidence administer remedies to soothe the lining membrane, and to check the discharge. The preliminary step, then, is the administration of a full dose of castor-oil, to which a few drops (5) of tincture of opium (laudanum) might be added, or a full dose of rhubarb or senna, or magnesia, or even a full dose of some saline remedy such as seidlitz powder, fruit salt, or the like.

Thereafter, if necessary, a little bismuth (see p. 854) and soda, with or without laudanum (5 to 10 drops), is likely to be all that is necessary. If that is still insufficient some of the stronger astringents may then be given, catechu or kino, with, if needful, laudanum and chalk mixture (see p. 844). In dysenteric conditions of the bowel ipecacuanha is most valuable (see p. 852) either alone or with opium as Dover's powder, and lead and opium, dilute sulphuric acid and opium, tincture of red gum with decoction of bael fruit, and preparations of iron. Injections of starch and opium (see p. 874), decoction of logwood, oak-bark, &c., might be resorted to in extreme cases, but it is only after failure with these that a physician would think of trying the effect of strong astringents like alum, copper, or zinc salts. Throughout the whole treatment care must be exercised in the dieting, broths and soups and beef-teas being avoided, well-boiled arrowroot and milk being the chief food for a day or two, and iced milk, and sips of iced water being given for thirst.

Remedies for Flatulence of the Bowel.

The remedies employed in wind affecting the bowel are the same as those used when the stomach is distended with wind (see p. 849). In addition, it is sometimes possible to cause the wind to be expelled by the use of an injection into the lower bowel. Often flatulence of the bowels will be greatly and quickly relieved by passing the long injection pipe of a syringe several inches up into the bowel, and leaving it there for 15 or 20 minutes; the pipe disconnected from the syringe is meant, and the one used for vaginal injections is best.

Remedies for Worms in the Bowel.

There are two classes of remedies used against intestinal worms: one class belongs to the order of strong purgatives, jalap (p. 861), scammony (p. 861), and gamboge (p. 862). These, simply by their ordinary purgative action, expel worms from the bowel as they expel any other contents. They are, therefore, called **Vermifuges** (Latin *vermis*, a worm; and *fugo*, I drive out). A second class of remedies kill the worms, and require afterwards a purgative to expel them when dead. To this class the term **Vermicide** is applied (Latin *vermis*, and *cædo*, I kill). Both classes are grouped together as **Anthelmintics**, which simply means remedies against worms, without implying whether the remedies destroy the worms or not (Greek *anti*, against, and *elmins*, a worm). The chief drugs destructive to worms—vermicides—are as follows:—

Remedies for Tape-worm (see p. 168).

Male-fern (*Filix mas*).
Areca-nut.
Kamala.
Kousso.
Pomegranate Root.
Turpentine.

Remedies for Round-worms (see p. 173).

Santonica.
Santonin.
Spigelia Root (Carolina Pink).

Remedies for Thread-worms (see p. 174).

Injections into the bowel of common salt, quassia water, lime water, iron, alum, tannin, or substances containing it, such as catechu, kino, rhatany, logwood.

Male-fern.—The parts of the male-fern (*Aspidium Filix mas*) used are the dried rootstock with the bases of the foot-stalk and portions of the root fibres. Its preparations are as follows:—

	DOSE.
Powdered Male-fern Root,...	60 to 180 grains.
Liquid Extract of Male-fern (Oil of Male-fern),..........	30 to 80 drops.
Oleo-resin of Aspidium—(American),..................	10 to 20 ,,

Use.—The male-fern root and preparations are used only for the expulsion of worms, and specially the tape-worm, for which it is the most successful remedy, if given properly. The person should, the day before its use, restrict the amount of food taken, and take chiefly liquids —soups, milk, &c. A dose of purgative medicine ought also to be taken to clear the bowels of all material which would protect the worm from the action of the drug. Next morning ½ to 1 tea-spoonful of the liquid extract is taken in a mixture with 1 or 2 tea-spoonfuls of fresh mucilage and peppermint water or milk to make 2 ounces. An hour later a full dose of castor-oil is taken. If the worm does not come away repeat the treatment.

Areca-nut is the seed of the *Areca Catechu* or betel-nut tree.

Powdered Areca-nut,.... Dose, ½ to ¾ ounce.

Besides being used as an anthelmintic, it is employed as a dentrifice in the form of a paste made of the powder. As an anthelmintic it is to be employed in a way similar to male-fern.

Kamala is a fine orange-red powder consisting of the hairs and glands obtained from the

surface of the fruits of *Mallotus philippinensis* (*Rottlera tinctoria*), which grows wild in Australia, Eastern China, India, Southern Arabia, and Abyssinia.

Dose, 30 grains to ¼ ounce.

After taking the powder the worm is usually expelled in a few hours; if not, the dose should be repeated in three hours.

Kousso or Cusso—the female flowers and tops of *Brayera anthelmintica*, a handsome tree of the rose order, native to Abyssinia.

Powdered Kousso,........ Dose, ¼ to ½ ounce.
Infusion of Kousso, ... ,, 4 to 8 ounces.
(¼ oz. kousso in coarse powder, 4 oz. boiling water; infuse in a covered vessel for 15 minutes, and drink when cold without straining.)

For the expulsion of tape-worm by this drug, it should be taken after the patient has fasted for a day. There is an active principle called **kosin** or **coussine,** of which a dose of 20 grains is sufficient, which does not tend to produce the nausea and vomiting sometimes occasioned by the infusion. In America there is a preparation used, the fluid extract of brayera, of which 8 fluid ounces is the dose.

Pomegranate Root Bark is the dried bark of the root of *Punica Granatum*, indigenous to South-western Asia, but now met with in all sub-tropical countries, grown on the shores of the Mediterranean.

Decoction of Pomegranate Root Bark, ... } Dose, 1 to 3 fluid ounces.
(2 ounces of sliced root in 2 pints of water, boiled down to 1 pint and strained.)

The pomegranate root bark is astringent, and requires therefore to be followed by a purgative when used for tape-worm. Several doses are often required; and it is not so active as the male-fern root. It contains two alkaloids, **pelletierine** and **iso-pelletierine.** Of the former there are two compounds, both used for tape-worm.

Sulphate of Pelletierine, ... Dose, 5 to 8 grains.
Tannate of Pelletierine,.... ,, 8 grains.

Five to 8 grains of the sulphate taken fasting, and followed in 15 minutes by a full dose of tincture of jalap (p. 861), causes expulsion of the whole tape-worm in nine cases out of ten. For children of 13 years, half this dose is given, and for infants one-tenth. Of the tannate 8 grains, followed in 2 hours by an ounce of castor-oil, is likely to be effective without colic or headache. Quicker action is obtained if black draught (p. 857) or the compound infusion of senna be used instead of the castor-oil, and the rules as to diet laid down for the employment of male-fern should be followed.

Turpentine is an oleo-resin which exudes from *Pinus australis* and other species of pine, and it occurs in tough yellowish masses. Distilled from this resin is the oil or spirit of turpentine of common use.

Oil of Turpentine,.................. Dose, 5 to 30 drops; as an anthelmintic, ½ to 2 tea-spoonfuls.
Confection of Turpentine,. .... ,, 1 to 4 tea-spoonfuls; as an anthelmintic, 1 to 2 ounces.
(Oil of turpentine 1 oz., liquorice powder 1 oz., clarified honey 2 ozs.)
Injection of Turpentine.
(Oil of turpentine 1 oz., mucilage of starch 15 ozs., the quantity for one injection.)
Liniment of Turpentine.
(Oil of turpentine 16 ozs., camphor 1 oz., soft soap 2 ozs.; dissolve the camphor in the oil, then add the soap and rub up till thoroughly mixed.)
Acetic Liniment of Turpentine—St. John Long's Liniment.
(Oil of turpentine 1 oz., acetic acid 1 oz., liniment of camphor 1 oz.; mix.)

Uses.—Turpentine when applied to the skin reddens it, producing a burning sensation, and if it be applied on a cloth and kept covered, a blister is produced. It acts, that is to say, as an irritant. Its vapour, when inhaled, similarly irritates the air-passages, causing a feeling of constriction of the chest. Taken internally in small doses, it produces a feeling of heat at the stomach, and in excessive doses acts as an irritant poison, setting up inflammation and ulceration. It is employed externally as a stimulant and counter-irritant in inflammations—applied, for example, to the chest and back in pleurisy, inflammation of the lungs, &c., and to the abdomen in inflammation of the bowel. Poured upon boiling water, a tea-spoonful at a time, it is used as an inhalation in chronic lung affections with discharge. It is used as a liniment for painful joints, neuralgia, sciatica, &c. It is given internally in doses of 10 drops, rubbed up with 30 grains powdered gum acacia and then with 1 ounce of water, in cases of bleeding from ulceration of the bowels in typhoid fever, and it is repeated every 2 hours, watchfulness being exercised lest sickness, vomiting, and symptoms of intoxication arise. It is also valuable in small doses as a stomach stimulant, especially in cases of hysterical flatulence, though its taste and

smell render it unpleasant and therefore not much used, and it also expels wind from the bowel, and in larger doses acts as a purgative. Given in the larger doses it is destructive to tape-worm, and is a valuable injection for thread-worms. It must not be forgotten that comparatively small doses are apt to irritate the urinary organs, and produce a feeling of heat and spasm about the urinary organs, difficulty of passing water, and pain in the small of the back.

Santonica is the unexpanded flower-heads of a species of *Artemisia*, imported from Russia, called also Levant worm-seed. The plant belongs to the same order as the daisy—Compositæ. From it **Santonin** is prepared, the active principle of the drug.

Santonica,...	Dose, 10 to 60 grains.			
Santonin,....	,,	1 to 4	,,	for a child,
		2 to 6	,,	for an adult.

Santonica and santonin are the best remedies for the round-worm, and are less destructive to the thread-worm. They should be given at night, followed by a brisk purgative on the following morning. A single dose of 2 grains of the latter has sufficed to expel 166 round-worms. It frequently affects sight, causing everything to appear yellowish or greenish yellow, and it colours the urine a bright yellow, giving rise also sometimes in children to inability to retain the urine. If it be given at night, the effect on vision is likely to pass off before morning. Excessive doses cause headache, giddiness, and vomiting, and arrest of the breathing. In cases of poisonous doses having been used, an emetic should be used to empty the stomach, hot stimulants should be administered, and artificial breathing maintained.

Spigelia, Maryland pink or worm-grass, found in shady woods in the southern parts of the United States of America, is employed in America to destroy worms.

Powdered Spigelia Root,...	Dose, 60 to 120 grains.
Fluid Extract of Spigelia,.	,, 1 to 4 tea-spoonfuls.

"The most usual and best form of the medicine is that known as 'worm tea,' namely, ½ ounce spigelia, senna and fennel-seed of each 120 grains, manna 1 ounce, boiling water 1 pint. Infuse. Dose, half a wine-glassful three times a-day for a child two years old." Excessive doses of the drug produce poisonous effects, hot dry skin, nervous excitement of a hysterical kind, pain in the forehead and eyes, stiffness and swelling of the eyelids, squinting, great muscular trembling, &c., and the remedies are wine, ammonia, and other stimulants.

Injections into the Bowel: Enemata: Clysters.

Injections are given for a great variety of purposes. Prepared foods are injected when, owing to some condition of gullet or stomach, foods cannot be administered in the usual way. These are called **nutritive enemata.** Then there are **stimulant enemata.** The most frequent object of an injection into the bowel is to clear out the bowel of its contents, either by mere washing out with water—**simple enemata,** or by the injection of purgative drugs—**purgative enemata.** Injections are also made to restrain bleeding and discharges of other kinds—**astringent enemata,** and soothing drugs may be introduced in the same way—**sedative enemata,** while they may be used against worms—**anthelmintic enemata.** A note of a few of these injections may be given. The injection is administered by means of a syringe (see Plate VIII). The syringe is first washed in hot water to make certain it is in order; then it is carefully emptied, and then filled with the injection material. The tube is then oiled and passed up into the bowel by means of a gentle turning movement, when it should go in quite easily. The injection must be made very slowly and steadily, to avoid irritating the bowel, and causing it at once to expel the whole material.

Beef-tea and Cream Enema.—Mix 4 to 8 ounces of strong beef-tea, an ounce of cream, ½ ounce of brandy, or 1½ ounces of port wine. This may be administered twice or thrice in 24 hours.

Peptonized Enema.—Mix 4 ounces of strong beef-tea with 4 ounces of milk gruel; add half a tea-spoonful of bicarbonate of soda and a dessert-spoonful of liquor pancreaticus (p. 847), and inject.

A Nutritive Enema may be made of any good broth (without vegetable, of course), or beef-tea made gelatinous, or of raw egg beaten up with milk and peptonized (see p. 847). A cupful of milk mixed with 2 tea-spoonfuls of Carnrick's beef peptonoids, with ½ tea-spoonful bicarbonate of soda and a dessert-spoonful of liquor pancreaticus, makes an excellent enema for children, half of this quantity being injected at a time.

Where such injections are used for any time, it is well to clear out the bowel occasionally by a copious injection of warm water. It is desired, of course, that the whole injection should be retained. It is an aid to securing this if the patient lies on the left side, and if after the enema has been given a folded napkin is kept firmly pressed against the outlet of the bowel

for a few minutes, till the desire to expel anything has passed away.

Simple Opening Enema.—Inject from a pint upwards of tepid water. This is used for emptying the bowel without further disturbance. It is exceedingly useful for children in convulsions or in fever, or simply for constipation. The bowels can be caused to act almost at once, if a sufficient quantity of water be injected. Even in the case of children a larger quantity than a pint may be used. It is the author's practice to inject as much as possible, *but slowly;* no harm can possibly be done. The result is that soon the bowel can retain it no longer, and everything is swept out almost in one rush. If any hard masses have been lying in the bowel, the large quantity of water, by distending the bowel, separates them from the walls of the canal, and allows of their being swept down.

Soapy Water Enema.—12 ounces of warm water with 1 ounce soap dissolved is somewhat more active than the simple water. About $\frac{1}{2}$ to 1 pint of it may be used.

Salt and Water Enema.—A dessert-spoonful to 2 or 3 table-spoonfuls of common salt are dissolved in 1 or 2 pints of warm water, and slowly injected. This is used when it is desired to act more than once upon the bowel. The action of the salt induces a temporary flux or catarrh of the bowel and recurring motions. It is useful in obstinate constipation and when head symptoms are present, symptoms of congestion of the brain, for example, and the desire is to bring down as much blood as possible from the head to the bowel, and keep it there.

Epsom Salt Enema.—Sulphate of magnesia (Epsom salt) 1 ounce, water 15 ounces. Used for a like purpose to the preceding.

Aloes Enema.—Mix 40 grains powdered aloes with 15 grains carbonate of potash and 10 fluid ounces of a thick solution of boiled starch. The whole of this may be injected when a purge is desired, but only 2 or 3 ounces of it is used to destroy thread-worms.

Assafœtida Enema is a very prompt way of removing wind from the bowels, especially in hysterical people. It is made with 30 grains of assafœtida, rubbed up with 4 ounces of water.

Glycerine Enema.—The injection of a tea-spoonful of glycerine is often sufficient to relieve constipation.

Castor-oil Enema.—Castor-oil 1 ounce, mixed with 12 ounces thick solution of boiled starch. To this 2 tea-spoonfuls of tincture of assafœtida may be added if flatulence exists.

Turpentine Enema.—Of turpentine oil 1 ounce, mixed with 15 ounces starch mucilage. This is useful in hysteria and hysterical flatulence. It is also employed to destroy thread-worms. In such a case 4 or 5 ounces only should be given, so that they may be retained for a time.

Opium and Starch Enema.—Half a tea-spoonful of laudanum in 2 fluid ounces of starch mucilage. This is employed to relieve pain, to check diarrhœa, &c. As it is desired to retain it, a small quantity only is injected. The quantity of laudanum is for an adult. For a child one ought not to use such a drug without the sanction of skilled advice, which would also indicate the amount. But in the case of diarrhœa in children, sometimes the injection of 2 or 3 ounces of a thick solution of starch alone is productive of much good, by coating over the irritated and inflamed bowel, and calming its excitability.

Astringent Enemata.—If the opium and starch enema fails in diarrhœa, others may be tried. To the starch 2 tea-spoonfuls of hazeline may be added, or half a tea-spoonful of the liquid extract of witch-hazel. In the purging of typhoid fever, if these fail the following may be tried:—Oil of turpentine 30 drops, tincture of kino 2 tea-spoonfuls, liquid extract of opium 10 drops, mucilage of starch 2 ounces. Another form is as follows:—Subnitrate of bismuth 20 grains, tincture of catechu 1 tea-spoonful, liquor hydrochlorate of morphia 30 drops, mucilage of starch 2 ounces; mix and inject the whole.

Enema for Piles.—Inject daily a tea-spoonful of tincture of witch-hazel in 3 ounces of tepid water.

REMEDIES WHICH ACT UPON THE LIVER.

Stimulants to the Liver.

In this section there has been already considered a number of drugs which stimulate the liver and promote the secretion of bile. These have all been at the same time purgatives, and drastic purgatives when given in large doses—podophyllin, &c. (see p. 864). There are, however, several drugs which excite the liver to activity in various ways without producing purging. These must now be noted. Subsequently the drugs will be mentioned which diminish the activity of the liver. The chief of these are dilute nitro-hydrochloric acid (see p. 841) and chloride of ammonium (see p. 843). In enlargement of the liver in tropical coun-

tries, the latter drug is said to be beneficial, in doses of 5 grains and upwards. Phosphorus (p. 826), arsenic (p. 822), and antimony (p. 853), by their slow action upon the chemical changes going on in the tissues, also modify the activity of the liver, exciting it to renewed activity.

Drugs which Depress the Liver.

Any substance which markedly irritates the bowels, such as purgatives, diminishes the activity of the liver, and thus a powerful purgative, which does not at the same time stimulate the liver, will quickly relieve that organ, when some acute disorder is threatened. Quinine and opium are also powerful depressants of the liver to be employed in similar circumstances. Nevertheless, nothing will so quickly help to relieve the liver as certain restrictions in the diet. The avoidance of sugar, starch, and fat, the three substances in the assimilation of which the liver is most concerned, will diminish the quantity of material with which the gland has to deal or which it is its business to store up. In cases of sluggish liver, if, with such restriction of diet, active exercise be freely indulged in, and the bowels be kept free by an occasional saline purge, the waste products of the activity of the kidney will be rapidly removed, to the great relief of the organ.

Section IV.—DRUGS WHICH ACT ON THE GLANDULAR SYSTEM.

Stimulants to Enlarged Glands:
- *Iodine;*
- *Lime* **and its Preparations—the Sulphide, Muriate, and Phosphate—Their Value in Scrofulous Diseases of Glands.**

Cod-liver Oil.

Roughly speaking there are two different sets of glands in the body. There are, first of all, those glands whose business it is to produce, from raw material supplied by the blood, some fluid which is to be employed in the body for some special purpose, or which is to be separated and cast out of the body as waste. Thus there are the salivary glands (p. 137), producing saliva to moisten the mouth, to aid in swallowing, and to assist in the digestion of starch; there are the gastric glands, producing the gastric juice, the pancreas, producing the pancreatic juice, the intestinal glands, producing the intestinal juice, the liver (also a gland), producing the bile, all for purposes of digestion; there are the kidneys separating urine from the blood, and the sweat glands of the skin separating water mainly, to be cast off from the body; and there are the minute glands embedded in every mucous membrane for the purpose of keeping it moist; the drugs acting on these glandular organs are discussed in other sections, those of the digestive tract in Section III., those of the skin in Section VII. But, in the second place, there is the large number of glands which produce no special material, which have no outlet at all, which are interposed in the pathways of some of the nutriment absorbed from the bowel (the chyle, see p. 200) as it passes onwards to enter the circulation, or interposed in the pathway of those vessels—the lymphatics—which pick up fluid from the tissues and pass it back into the circulation (see p. 203). These glands have no outlet because they manufacture no special juice. Their business is to work up the chyle absorbed from the bowel, or the lymph absorbed from the tissues, by acting upon it in some way unknown to us, and fit it for becoming part of the circulating blood. Now if we think what an important function this is, a most vital part of the blood-forming business, if we realize how profoundly any serious disorder of the activity of these glands will affect the health of every tissue and organ of the body, we shall understand how valuable information would be as to the drugs which act upon these glands and as to the nature of their action. Let us take an illustration. "The glands of the bowels" is a popular phrase for the mesenteric glands (p. 201), and we know what apprehension is excited when there arises any suspicion of disease affecting them. The apprehension is well grounded. For we have already described (p. 200) how a large portion of the nutritive material of the food is picked up by vessels in the bowel, called lacteals, and carried direct to these mesenteric glands before being poured into the current of circulating blood. Any disease which seriously affects these glands may at once interfere with the course of this nourishing material, and may prevent its ever reaching the blood. It is not, then, to be wondered at if rapid wasting of body

and exhaustion of strength are among the early and chief signs of such glandular disease. Scrofula (p. 431) is another illustration of the great importance of the lymphatic glands in the general nutrition of the body. Again, the important parts these glands play in the interception of poisonous material has been pointed out (p. 203), and the significant share they have in disseminating such diseases as cancer has been referred to (p. 434). All these facts illustrate how valuable would be any drug which was known to have direct and powerful effects upon glands, if it were possible to give it any direct application in disease. As a matter of fact, however, it can hardly be said that there are any medicines which have a specific action limited to glands. They can be acted upon only by that class of remedies which have a general effect upon the nutrition of the whole body by influencing the character of the blood or by modifying tissue change. The remedies which have these effects have already been noted in Sections I. and II. It will, therefore, be sufficient merely to mention those specially in use in affections of glands, and reference can then be made to the page where their action is more fully described.

Iodine, in some form, is a favourite remedy in chronic swelling of glands, and in scrofulous conditions. Sometimes it is applied as tincture, painted over the enlarged gland, sometimes it is given along with a preparation of iron, in the form of iodide of potassium; and a specially useful remedy, under such circumstances, is the syrup iodide of iron. For these preparations and their uses see p. 825.

Lime or calcium preparations stand probably next in regard for supposed virtues in glandular affections, specially such as are of a tubercular or scrofulous character (see p. 430). The main preparations and uses of lime have already been mentioned on p. 844. But there are other preparations, not named on that page, used almost exclusively for scrofulous and other enlargements of glands, for bone diseases, and in wasting diseases. They are as follows: —

	DOSE.	
Sulphide of Calcium (or Sulphurated Lime), ...	$\frac{1}{10}$ to 1 grain.	
Chloride of Calcium[1] (Muriate of Lime), ...	1 to 3 grains	for children.
	10 to 20 ,,	for adults.
Phosphate of Lime, ...	10 to 20 ,,	
Hypophosphite of Lime, ...	5 to 10 ,,	

[1] This is not the "chloride of lime" employed as a bleaching powder, and for purposes of disinfection, the proper name of which is *chlorinated* lime, though it is commonly called "chloride of lime." The two must not be confounded.

The so-called sulphide of calcium is principally used to check the formation of matter. If a gland be inflamed, and suppuration be feared, this preparation is given in doses of from $\frac{1}{10}$ to $\frac{1}{2}$ grain in pill four or five times a day, and is sometimes successful in checking it. In larger doses it is likely seriously to irritate the stomach. The chloride of lime was strongly recommended by the late Dr. Warburton Begbie, of Edinburgh, in the case of children with swollen glands of the neck, or children who suffered from weakness, loss of appetite, and diarrhœa, of a scrofulous character. "The cases in which I have had occasion most frequently to employ the muriate of lime have been instances of struma (scrofula), the most notable feature of which was the enlargement of the lymphatic glands in the neck. In the earlier cases which fell under my observation, recourse was had to the remedy, either because what appeared to be a fair trial had already been given to iodine, or its preparations, chiefly the iodide of potassium, and syrup of the iodide of iron, or to cod-liver oil. Frequently both iodine and cod-liver oil had been employed without appreciable benefit, or it had happened that these remedies had disagreed. Under such circumstances, then, muriate of lime was prescribed. For several years, however, with a growing and latterly extended experience of its virtues, I have not hesitated to order the remedy when no such proof was afforded, either of the failure, or of the intolerance on the patient's part, of the other medicines. I am not able to affirm that the remedy has always, that is, in every case, answered my expectations. . . . But it is in my power to assert, that many instances of very great enlargement of the cervical glands (glands of the neck) and several examples of other maladies, which will be shortly referred to, have apparently yielded to its use." One of the other maladies referred to is that met in childhood with symptoms resembling those of consumption of the bowels (tabes mesenterica, p. 166); and in it he observed the use of the remedy to be followed by the cessation of protracted diarrhœa and exhausting perspirations, by a diminution of fever, by improvement in appetite, the gaining of flesh, and a gradual restoration to the condition of health. Children suffering from loss of appetite, pallor, loss of flesh, protuberant belly, wasted limbs, and feverishness, he found greatly benefited by its use. He says that in such cases it requires to be taken for a considerable time—for weeks, it may be even months—before its beneficial effects are visibly produced. He

recommends it to be taken after meals in milk, twice or thrice daily. It may be employed in the form of the solution of chloride of lime, of which 15 drops contain about 10 grains. This dose may be given to young persons (and less in proportion to children) thrice daily, and may be gradually increased to 30 or 40 drops. Too large a dose is likely to produce loss of appetite, sickness, and pain in the stomach. The phosphate and hypophosphite of lime are employed in similar affections, usually in combination with other substances, as compound syrup (see p. 817).

Cod-liver Oil is, however, perhaps of more value in glandular affections than even iodine or lime preparations. It is the oil extracted from the fresh liver of the cod, *Gadus Morrhua*, with the aid of heat. Its beneficial effects are not due to any specific action on glands or any other organs, since it is a food rather than a medicine; but it is much more readily absorbed and passed into the circulation than other oils. Not only does it thus readily gain access to the tissues, but it is also readily taken up by them, and thus it stimulates nutritive changes all over the body, and improves the general health. It quickly improves the quality of the blood, and is thus a blood tonic, while it is to be remembered that it can gain the blood current only by passing through the lymphatic glands. It may be applied externally in the case of feeble children, who cannot bear it on the stomach, by rubbing it into the skin. It appears to be of some value, even for nutritive purposes, when used in this way. But it is also used externally for scaly skin diseases to soften the skin, in psoriasis, for example. Internally it is given in all cases of defective nutrition, specially in glandular, scrofulous, and consumptive affections. For rickety children it is usefully combined with preparations containing lime, such as Parrish's chemical food (p. 817), or the compound syrup of hypophosphites. In all chest affections, specially in chronic bronchitis, it is very valuable. It exerts a most notable influence in diminishing the amount of the expectoration. In consumption of the lungs it is constantly administered, not because it directly tends to cure the disease, but because by its nutritive properties it does something to save the tissues that are specially subject to the wasting process. From time immemorial it has been a popular remedy for chronic gout, rheumatism, rickets, and scrofula. It acts as a tonic in nervous diseases, and may be combined with iron preparations, for neuralgia, hysteria; and in convalescence from all acute diseases, more particularly in damp and changeable climates, are its beneficial effects shown.

As a rule it is not to be given when the bowels are loose, lest the diarrhœa be increased. But if the diarrhœa arises from conditions of general weakness, &c., which the oil might help to rectify, it should be cautiously tried, in small quantities, in combination with something slightly astringent, such as chemical food. It will often prove useful in constipation.

Cod-liver oil is best given not immediately after food, and certainly not on an empty stomach, but an hour or two after food. Small quantities should be begun with, and they may be slowly increased, as the person becomes accustomed to them. Sometimes a dose can be tolerated without discomfort at bed-time, when it would occasion sickness at any other period of the day. Those who after patient trial cannot get accustomed to its use, ought not lightly to give up all attempts, but should try one or other of the numerous disguises now in the market—cod-liver oil emulsion, cod-liver oil and malt extract, peptonized cod-liver oil and milk (Carnrick's), &c. Many persons find it easily and agreeably taken when it is floated on the surface of claret. Its dose is from 1 tea-spoonful to 2 table-spoonfuls.

When it is persistently rejected by the stomach, combining it with pure ether should be tried—10 drops of pure ether to 1 tea-spoonful of the oil. The ether aids its digestion by stimulating the flow of pancreatic juice.

SECTION V.—DRUGS WHICH ACT ON THE LUNGS AND AIR-PASSAGES.

Remedies which Stimulate the Lungs and Air-passages.

Stimulants to the Circulation in the Lungs and Air-passages:
Ammonia, Digitalis, and Aromatic Oils.

Stimulants to Secretion from the Air-tubes—Expectorants:
Heat, Ammonia, Alcohol;
Senega; Balsams of Peru and Tolu;
Copaiba and Cubebs; Ammoniacum, Galbanum, Myrrh, Benzoin, Tar, &c.;
Ipecacuanha;
Inhalations of Carbolic Acid, Creasote, Iodine, Turpentine, Essence of Pumiline Pine, Eucalyptus Oil.

Remedies which Soothe the Lungs and Air-passages.

Remedies which Lessen the Circulation in the Lungs:
Heat and Blisters;
Antimony, Aconite, and Ipecacuanha.

Remedies which Diminish Expectoration:
Acids and Belladonna.

Remedies which Relieve Spasm:
Lobelia, Stramonium, Conium, and Tobacco.

Speaking broadly we may say there are two chief ways by which the lungs and air-passages can be influenced by drugs—the one is by stimulation, the other is by a soothing or depressing action. In order to understand how these effects may be brought about, it is necessary to recall some of the chief facts already mentioned in the section describing the structure and functions of the lungs and air-passages (p. 249). The lungs consist essentially of a large number of minute vesicles, cells, or sacs filled with air, communicating with one another by means of fine tubes—the bronchial tubes, and finally communicating with the outside air. In the walls of these air-cells are situated the vessels through which the blood flows; and while the blood flows through these vessels, it is exposed on all sides to the air of the vesicles, only a thin wall intervening between it and the air, so that exchanges readily occur between them. The tubes or air-passages have layers of involuntary muscle in their walls, by whose contraction the diameter of the tubes is diminished. The larger tubes have plates or partial rings of gristle in their walls to prevent their complete closure, but the smaller tubes are not so provided, and the contraction may be so great as practically to block the passage. Then the inner lining membrane of the bronchial tubes contains small mucous glands, which secrete a material for keeping the membrane moist, and this lining membrane has on its inner surface, except in the case of the finest terminations of the bronchial tubes, fine hair-like processes, or cilia (p. 252), which, moving always in one direction, sweep any material in the tubes upwards to the mouth, whence it is in time expelled. Now, it is plain that the gaseous exchanges going on in the lungs will materially depend upon the rate at which the blood is flowing through the vessels in the walls of the air-cells. This will, to a large extent, depend on the force and frequency of the contractions of the heart, for it is by the contractions of the heart that the blood is driven from the right side of the heart through the lungs, being purified on its course, to the left side, whence it is distributed throughout the body. This circulation through the lungs will, therefore, be quickened by any means which strengthen and stimulate the heart. Remedies which have this effect have been already named in Section II., and the chief of them are ordinary stimulants, ammonia, digitalis, squill, aromatic oils, such as have been named on p. 848 for flatulence, and senega. Another kind of stimulating effect is that which acts specially upon the lining membrane of the air-passages and their glands, increasing the amount of material poured out, relieving a dry and swollen condition of the membrane, and providing a larger supply of material to be swept out. This effect is produced by warm foods and drinks, and by ammonia and other alkaline remedies (see p. 843), by sulphur, by ipecacuanha, iodide of potassium, senega, squills, antimony, turpentine, camphor, balsam of Peru and Tolu, and aromatic oils. For example, in the early stage of

COMMON THORN APPLE – THORNY APPLE OF PERU.
DEVIL'S APPLE – JAMESTOWN WEED.
(Datura Stramonium)

WOODY NIGHTSHADE or BITTER SWEET.
FELLOWWOOD.
(Solanum Dulcamara.)

CUCKOO PINT or WAKE ROBIN.
LORDS & LADIES. COMMON ARUM.
(Arum Maculatum.)

acute bronchitis the lining membrane is swollen, red, and dry, great difficulty of breathing is experienced, and shrill wheezing sounds are heard widely spread over the lungs, and there is a dry and very irritable cough. The use of a remedy which causes the glands to pour out a copious secretion will speedily relieve the inflammation, will by moistening the membrane diminish its irritability, and will, thereby, greatly relieve the breathing. Again, in the latest stage of the same disease, and in others, accompanied by a scanty tough spit, which maintains a constant cough owing to the great difficulty of getting the tough phlegm swept up, any remedy which will increase the secretion, and so produce a more abundant and watery spit, will greatly relieve the symptoms. But, still more, the stimulating effect of various remedies is experienced by the muscular coat of the bronchial tubes, and by the cilia of the surface of the lining membrane, and the result of their increased activity is to sweep up more vigorously any offending material lying in the tubes. Cough will thus be increased, and that may seem at first blush a disadvantage; but so long as cough is the means of removing material which, if allowed to accumulate, will speedily fill up the air-passages, and render continued breathing exceedingly difficult or next to impossible, it is not a disadvantage, but a necessity. Finally, it has been pointed out in Section IX. A, p. 256, that the whole process of breathing is under the influence and control of the nervous system, and remedies may be given which will increase the excitability of the nerves of respiration, and so stimulate the breathing process.

Now all these actions may be reversed. Thus, the quantity of blood flowing through the lungs may be diminished and its speed lessened by means, such as mustard applications, which withdraw the blood to other organs, or by means which weaken the heart's action, such as aconite, antimony, and ipecacuanha. The quantity of mucus secreted by the glands of the bronchial tubes may be diminished by belladonna, stramonium, and hyoscyamus; and this effect it is very desirable to produce in chronic bronchitis and other diseases, with copious expectoration. The irritability of the whole lining membrane of the tubes may be lessened by warm food and warm applications, and by drugs like opium, ether, and chloroform. This effect it is very necessary to produce for the relief of cough of a dry, hacking kind. Such a cough is often due, not to the presence of any material to be expelled, but to the great irritability of the lining membrane, so that a mere whiff of cold air will start off a severe fit of coughing. The excitability also of the muscular coat of the tubes may be lessened, so that they tend to remain relaxed, allowing the tubes to be widely open. This is a most desirable result to achieve in spasmodic conditions, such as that of dry asthma, and which yields for a time at least to chloroform, ether, and nitrite of amyl (p. 837). Belladonna, stramonium, hyoscyamus, lobelia, tobacco, opium, and Indian hemp have a similar effect.

We see, then, that in disease of the lungs and air-passages the chief remedies employed are such as have either a stimulating or a soothing effect on the circulation, or on the secretion of mucus, or on the nerve and muscle part of the breathing apparatus. It may be noted that some stimulating remedies have an influence in all these various ways. Ammonia, for example, stimulates the circulation, the secretion from the glands, and the respiratory nerves; on the other hand, ipecacuanha depresses the circulation, but stimulates secretion and the nervous apparatus.

REMEDIES WHICH STIMULATE THE LUNGS AND AIR-PASSAGES.

Stimulants to the Circulation in the Lungs and Air-passages.

It is unnecessary to go over such remedies as stimulate the circulation in the lungs in detail. All heart tonics and stimulants (see p. 832) will naturally strengthen the circulation through the lungs. But it may be pointed out that a purplish or blue appearance of the skin of the face and lips is an indication of the need of some such stimulant. Ammonia, in the form of smelling salts, may be of use if the weakness is but temporary, and the carbonate of ammonia, in 5-grain doses repeated several times daily, and the aromatic spirit of ammonia (p. 843) are valuable, while tincture or infusion of digitalis with ammonia is, in weak conditions of the heart, a most effective combination. The pungent aromatic oils (p. 849) have a similar, though less durable, effect. Then a brisk purge, by unloading the liver and bowels, quickens the circulation through the lungs.

Stimulants to Secretion from Bronchial Tubes—Expectorants.

Expectorants is the term applied to such remedies as assist in the expulsion of phlegm from the air-passages. Now, a drug may be an expectorant which simply loosens the spit, so as

to permit it to be more easily brought up. Warmth has such an effect, and may be applied to the chest in the form of a hot poultice, or may be employed in the shape of warm air or steam which is inhaled. Another drug may be an expectorant which simply increases the mechanical force brought to bear in coughing up the spit. Thus an emetic acts mechanically; the act of emptying the stomach serving also to expel material collecting in the bronchial tubes. For this purpose ipecacuanha wine is best, or if there is much depression an emetic dose of carbonate of ammonia—30 grains. The chief expectorants, however, are those which by their stimulant, or slightly irritating effect, increase the flow of blood to the lungs and air-passages and thus cause an increased flow of secretion. All the drugs mentioned under stimulants to the circulation will do this, but the chief are ammonia, alcohol, squill, senega, and balsams. Ammonia and alcohol have been already sufficiently discussed. Squill and its preparations have been noted on p. 833. Let it be remarked here that the fact that squills has a stimulating effect or irritating effect ought to prevent its promiscuous use in every case of cough, bronchitis, &c. Syrup of squills and ipecacuanha wine are the two domestic remedies for cough and lung affections. To the ipecacuanha wine there is little objection, to the syrup of squills there is often much. If cough is the result of an irritable condition of the bronchial tubes where there is little or no phlegm to expel, its use can only be hurtful by adding to the irritation, and in acute attacks of bronchitis it ought not to be employed. In chronic bronchitis, with copious spit, it is useful.

Senega is the dried root of *Polygala Senega*, a native of North America. It contains an active principle, **senegin** or **saponin**. Its preparations are:—

Powdered Senega, ...	Dose,	10 to 20 grains.
Infusion of Senega, ...	,,	1 to 2 ounces.
Tincture of Senega, ...	,,	½ to 2 tea-spoonfuls.

Uses.—The powder of senega taken as a snuff acts as a powerful irritant on the nose, causing cough, sneezing, and a discharge. In any form it acts similarly on the stomach as an irritant, more or less powerful according to the dose, large doses causing heat, pain, sickness, and diarrhœa. It similarly stimulates the lining membrane of the air-tubes after it has passed into the blood, increasing the quantity of blood flowing in it, and the secretion from it, and increasing cough by the increased irritability. It is therefore used in the later stages of bronchitis when the spit is abundant, but ought not to be used in the inflammatory stage of any lung affection, which it can only aggravate. It probably increases the strength of the heart, and consequently in congestion of the lungs because of failure of the heart and threatened blocking of the lungs, it is of great value with carbonate of ammonia and tincture of digitalis.

Balsam of Peru is obtained from a tree, *Myroxylon Pereiræ*, growing in the state of San Salvador in Central America. The bark of the tree is beaten with a blunt instrument until it separates from the trunk without breaking off. After a few days the loosened bark is charred by torches, and in the course of a week the charred pieces fall off. From the bare trunk the balsam exudes and is licked up by rags applied to it, from which the balsam is afterwards obtained by boiling in water. The bark of the tree is not loosened all round, but only in strips, so that the vitality of the tree is not destroyed. On the following year the untouched strips are similarly treated. Thus an annual supply of balsam is got for thirty years, with the exception of once every five or six years, when the tree is untouched, in order that it may not be too soon exhausted.

Balsam of Peru,........ Dose, 10 to 30 drops mixed up with gum or white of egg.

Uses.—The balsam is a stimulant, specially to mucous membranes, stimulating stomach and bowels, as well as the heart and kidneys. It is for chronic bronchitis that it is most frequently given internally, in which it lessens the expectoration. It is also used in dysentery because of its stimulating action, and in other cases of discharge from mucous membranes, such as from the nose, ears, and genital organs. It is used in gleet. It is reputed also as an antiseptic and as destructive to parasites. It is much used in Germany for itch, being more agreeable than sulphur ointment. The person first takes a prolonged warm bath, soap being freely used. Thereafter the body and specially the parts affected are rubbed with 40 drops of the balsam, and this is repeated thrice daily for two days, when the cure is complete. It affords great relief in cases of itching (pruritus, see p. 323), being applied pure by means of a brush, and it is employed for ulcers and sores, chilblains, and sore nipples. An ointment for the destruction of lice is made with 20 parts of the balsam, 50 of olive oil, and 100 of petroleum.

Balsam of Tolu is obtained from the *Myroxylon Toluifera*, of New Granada. It exudes from the trunk of the tree after incisions have been made in the bark.

Balsam of Tolu,	Dose,	10 to 20 grains.
Syrup of Tolu,	,,	1 to 3 tea-spoonfuls.
Tincture of Tolu,	,,	15 to 30 drops.

Tolu balsam has an effect similar to balsam of Peru, and is used chiefly for cough mixtures, in cases of chronic bronchitis. It is not used externally to the same extent as the latter; but is an ingredient of compound tincture of benzoin or Friars' balsam, used for wounds. In the latter combination it is very useful as an inhalation for tickling cough and hoarseness. A tea-spoonful is poured on the surface of boiling water and the vapour inhaled.

Copaiba is an oleo-resin obtained from incisions made in the trunk of *Copaifera multijuga*, found chiefly in the valley of the Amazon.

Copaiba,	Dose,	½ to 1 tea-spoonful.
Oil of Copaiba,	,,	5 to 20 drops mixed with gum or yolk of egg.

Uses.—Copaiba is a stimulant to mucous membranes, causing warmth in the stomach, and irritation, sickness, &c., if used in too large quantities. It is excreted by the kidneys, bronchial tubes, and skin, the unpleasant characteristic smell being readily perceived from the patient. In course of being expelled by the organs named it exerts a healing and antiseptic effect upon their lining membrane. It is thus a useful expectorant in chronic bronchitis, especially if the discharge be foul-smelling. But it is chiefly used for affections of the genito-urinary organs; for which, however, it ought not to be employed if the kidneys are the seat of any inflammatory affection.

Cubebs, in doses of 30 to 120 grains, is employed in the same circumstances as copaiba.

Various other oils and resins have similar effects, such as **Ammoniacum** (dose:—10 to 30 grains), a gum-resin, exuding after puncture from the stem of *Dorema ammoniacum*, found in Persia and the Punjaub; **Galbanum,** a gum-resin derived from *Ferula galbaniflua*, of India and the Levant, of which the dose is 10 to 30 grains; **Turpentine, Camphor, Benzoin.**

Benzoin is a gum-resin obtained from a tree —*Styrax Benzoin* or Benjamin-tree—indigenous to Sumatra, Borneo, and Java, and cultivated in the first-named place to a considerable extent. It is also called Gum Benjamin. It derives its properties from the benzoic acid it contains to the extent of 10 to 20 per cent. Its chief preparation is Compound Tincture of Benzoin—Friars' balsam—which is used mainly for wounds.

Benzoic Acid is contained not only in gum benzoin, but also in balsam of Peru, balsam of Tolu, and storax. It is an ingredient in the compound tincture of camphor—paregoric elixir —and the ammoniated tincture of opium. When taken internally benzoic acid creates a feeling of heat in the throat and of general warmth. It stimulates the lining membrane of the air-passages; and is used in chronic bronchitis, tending to diminish the excessive secretion. It also excites the secretion of urine, and stimulates the lining membrane of the bladder, being used in cases of chronic inflammation. Its dose is 10 to 15 grains.

Storax, a liquid balsam derived from the *Liquidambar orientalis*, is contained in the compound tincture of benzoin. Its actions and uses are similar to those of balsam of Peru. It is, like it, used for itch in the form of an ointment, of 1 oz. of storax and 2 drachms of olive-oil. After a warm bath the whole body except the head is rubbed with this, and one application is usually enough, but a second had better be given in twenty-four hours. It is not irritating to the skin, and this is a great advantage. It is used internally in chronic colds, especially of the lungs, but also of the urinary organs, in doses of 5 to 20 grains.

Myrrh, a gum-resin exuding from the stem of *Balsamodendron Myrrha*, of Arabia Felix and Abyssinia, is also used under like circumstances. Its dose is 10 to 30 grains. Of it there is a tincture (dose ½ to 1 tea-spoonful), which is an admirable astringent as a wash for spongy gums or ulcerated throat. It is given in combination with iron and aloes in pill (see p. 859). All these substances are only employed very occasionally in chronic bronchitis with profuse discharge, and after acute symptoms have passed.

Tar (Pix Liquida) is obtained by the destructive distillation of various pines, *Pinus palustris* and *Pinus sylvestris*. The preparations of tar used in medicine are:—

Tar Pills, 20 drops of tar made into pills with flour.
Tar Water,..................Dose, 1 or 2 pints daily.
(A mixture of 1 part tar and 3 parts powdered pumice-stone well shaken for 5 minutes with 10 parts of water.)
Syrup of Tar,...............Dose, ½ oz.
Tar Ointment.

Uses.—Tar is a stimulant to the skin and mucous membranes. Its chief use is in skin diseases, for which the ointment is applied, or

the tar itself or oil of tar rubbed in on the affected patches, while tar pills or tar water or syrup are taken internally. It is also of value when employed as a soap. It is a stimulant also to the lining membrane of the air-passages, diminishing expectoration in chronic bronchitis and other chest affections, for which it is best used as vapour. A little tar is mixed with the twenty-fourth part of its weight of carbonate of potash and placed in a cup set in hot water over a night-lamp. The apartment is thus allowed slowly to be filled with the fumes, which are inhaled by the patient. The tar water may be used as an inhalation.

Oil of Birch-tar (Oleum Rusci) is used as an inhalation in chronic bronchitis: 10 drops are slowly converted into vapour by heat in a chamber in which the patient is.

Horehound, the leaves and tops of a perennial herb, *Marrubium vulgare*, of the labiate order, has long been a popular remedy in chronic cough and other affections of the air-passages, attended by much defluxion. It is stimulating, may be used as a tonic in dyspepsia, and also stimulates the skin and kidneys. In chronic rheumatism and in intermittent fever it has also been used. The infusion may be made with 1 oz. of horehound to 1 pint of hot water, and of this a wine-glassful is the dose. A syrup is made by adding sugar to the infusion.

Hyssop—*Hyssopus officinalis*, of the natural order Labiatæ—is another plant much used in domestic medicine, for purposes similar to those for which horehound is employed. A drachm of the herb to a pint of hot water yields an infusion, used as a tonic in dyspepsia, in chronic bronchitis, and as a gargle for sore-throat. It has also been employed in absence of the monthly illness.

Elecampane—the root of *Inula Helenium*, of the order Compositæ—was one of the most popular of ancient remedies. It was a domestic remedy for chronic bronchitis, dyspepsia, absence of the monthly illness, and in chronic eruptions of the skin. For these its stimulating properties made it sought after. It has recently been claimed for it that it could destroy the germ of consumption, the tubercle bacillus (p. 393). It is given as a decoction, made by boiling ½ ounce of root in 1 pint of water. The dose is from a half to one wine-glassful. It contains a substance, **inulin,** allied to starch.

Ipecacuanha has already been discussed on p. 852. It is well, however, to note here again its action so far as the lungs are concerned. It differs materially in action from senega, the balsams, myrrh, &c., already considered in this section, in this, that it aids the expulsion of discharge from the lung both by increasing the force of cough and by increasing the fluidity of the spit; but at the same time it does not excite but calms the circulation in the lungs. Now the other expectorants excite the circulation, and in any inflammatory conditions are apt to do mischief, and are, therefore, avoided. Ipecacuanha, however, from its reverse action, can with safety be employed even though acute inflammation be present, and is, indeed, in many such cases the appropriate remedy. It is very useful in the dry inflammatory stage of bronchitis, which it relieves by increasing the natural secretion of the parts and causing the irritable inflamed membrane of the air-passages to become moist.

Inhalations and Sprays are much employed in treating affections of the air-passages, as it has been shown that vapour of substances drawn into the lungs with the breath can penetrate to the inmost recesses of the lungs, and can also be absorbed from the lining membrane and pass into the circulation. There are various methods of employing substances by inhalation. The substance may be converted into vapour by the aid of dry heat, and the air of the apartment in which the patient is may thus be impregnated with the remedy, so that the patient inhales it without further trouble; or the material may be converted into vapour by means of boiling water, and the vapour inhaled along with the steam from the water. This can be done by means simply of a jug half filled with boiling water. The patient brings his mouth down to the opening of the jug, and a towel is arranged round the mouth and the edge of the jug to prevent escape of the vapour. The towel is so arranged that the nostrils are free, and the patient should inhale by the mouth, but breathe out by the nostrils. Instead of a jug, one of the various forms of inhalers in the market can be used (see Plate XIX. 3 and 4, and section on Medical and Surgical Appliances). Then the inhalation may be effected by means of a form of respirator. One of the best kinds is shown in Plate XIX. 2. It consists of a metal piece which fits over the mouth. The wall of the case is at one part double, and is perforated with small openings. The outer part of the double wall is movable on a hinge; and a piece of lint soaked in the medicated solution is placed between the two parts. The respirator is then fixed over the mouth, and air drawn through the soaked lint. In this case also the patient should inhale by the mouth and exhale by the nose.

Medicated solutions are also applied by means of spray producers (see Plate XIX. 1). The patient opens his mouth widely and the spray is directed to the throat, the patient inhaling at the same time. By this means the air-passages below the top of the windpipe do not receive nearly so much of the remedy, the back of the mouth and top of the gullet intercepting most of the material. Finally, remedies may be introduced into the air-passages in the form of smoke from a pipe, cigarette, or cigar, the remedy being mixed up with tobacco or used instead of tobacco.

The substances commonly employed in one or other of these ways may be either stimulating or soothing, or may be employed chiefly for antiseptic properties to destroy a foul smell, in cases where the expectoration is fœtid, or for astringent purposes for relaxed throat or hoarseness, or to control bleeding from the throat.

Stimulating and Antiseptic Inhalations.

Vapour of Carbolic Acid.
,, Creasote.
,, Benzoin.
,, Iodine.
,, Pine Oils.
Spray of Sulphurous Acid.
Vapour of Tar.
,, Turpentine.
,, Terebene.
,, Oil of Thymol.

Soothing Inhalations.

Vapour of Water.
,, Conium.
,, Nitre, as Nitre Paper.
,, Stramonium.
,, Tobacco.
Spray of Ipecacuanha Wine.

Astringent Sprays.

Alum Spray (10 grs. to 1 oz. water).
Sulphate of Iron Spray (2 grs. to 1 oz. water).
Lactic Acid Spray (21 grs. to 1 oz. water).
(For use in diphtheria.)
Tannic Acid Spray (60 grs. to 1 oz. of water).
(For bleeding.)

Carbolic Acid and Creasote are used as inhalations with the Coghill inhaler, already mentioned, in chronic bronchitis, and also in consumption, in both of which they are very useful. The strength of carbolic acid is 60 drops to 1 ounce of water, and of this 10 drops are placed on the lint of the inhaler. A solution of spirit of creasote of the same strength may be used, or 12 drops are placed on 8 oz. of boiling water. Creasote and carbolic acid may be mixed, 60 drops of each, 2 drachms of glycerine, and 1 oz. of water, of which use 10 drops.

Compound Tincture of Benzoin is used for hoarseness and in chronic bronchitis. A teaspoonful is poured on the surface of boiling water.

Iodine is employed in cases of offensive spit, and in chronic bronchitis. Thirty drops of tincture of iodine are mixed with 4 ounces of cold water, and the vapour is cautiously inhaled.

Turpentine and Pine Oils are the most commonly used of inhalations in cases of chronic bronchitis with excessive expectoration, and as antiseptics in cases of consumption. It has been asserted that the atmosphere of pine forests is extremely beneficial in lung affections, and the use of such an inhalation is an attempt to create an artificial atmosphere of the same kind. One ounce of turpentine to 5 ounces of cold water are used with a common inhaler. **Terebene,** prepared from it, may be used with the Coghill inhaler, 10 drops being placed on the lint. Of pine oils the oil of *Pinus sylvestris* (for wood oil) and *Pinus pumilio* are employed in a similar way, or may be used with boiling water as follows:—40 drops are mixed with 20 grains of carbonate of magnesia, and that with 1 ounce of water. One drachm (60 drops) is placed on hot water and inhaled.

Oil of Eucalyptus—the Blue Gum-tree—is used for inhalation. Ten drops on boiling water may be inhaled, or 5 to 10 drops may be placed on the lint of the Coghill inhaler, or it may be similarly used when mixed with terebene, in equal proportions. It is also given internally in chronic bronchitis and consumption as tincture, of which 15 to 60 drops are a dose, or in emulsion with mucilage of ordinary gum or gum tragacanth, 2 drops of the oil being the dose.

Sulphurous Acid Spray is employed chiefly for sore throats, hoarseness, &c. The strength employed is 5 drops sulphurous acid to 1 ounce of water.

Oil of Thymol is employed for antiseptic purposes, 10 grains being mixed with 20 of magnesia and 3 ounces of water, one drachm being inhaled from hot water.

REMEDIES WHICH SOOTHE THE LUNGS AND AIR-PASSAGES.

Remedies which Lessen the Circulation in the Lungs.

Nothing so quickly allays irritability of the lungs and air-passages as a diminution in the quantity of blood flowing through them. This diminution is not to be effected by creating

difficulties to the flow of blood. On the contrary, everything which, by dilating the blood-vessels for example, permits the blood to flow more easily, will afford relief. What is desired, however, is the withdrawal of the blood to some other part of the body, and so getting rid of determination of blood to any particular part of the respiratory system, which is the first stage of inflammation. The chief means of effecting this are (1) heat, and (2) counter-irritation, that is the use of mustard poultices or blisters. For example, a mustard foot-bath would produce speedily relief, or a large hot poultice applied to the back or chest. A mustard poultice speedily reddens the skin, that is, withdraws blood to the surface, and a blister has a similar effect, its action being less fleeting. Heat may be applied directly to the air-passages in the form of steam. The inhalation of the steam of hot water from a jug will act by causing dilatation of the vessels of the upper air-passages, and will thus aid the onward progress of the blood. The steam may be poured into the apartment occupied by the patient by means of a bronchitis kettle (see Plate VIII.). Brisk purgatives, by taking the blood down to the bowels, will relieve the circulation in the lungs. For this purpose saline purgatives are best, since they also promote secretion of liquid mucus, and aid expectoration.

A second way of lessening the circulation is by the use of remedies which diminish the force and frequence of the heart, such as aconite (p. 834), antimony (p. 853), and ipecacuanha. The advantage of ipecacuanha has already been noted above, in that while depressing the circulation it increases the secretion of mucus, and strengthens the expulsive effort.

It is important also to note that rest and complete cessation of all muscular effort is an important aid to treatment designed to remove irritability of air-passages. It is common, for example, to observe how the slightest movement will cause certain kinds of cough to recommence immediately. Patients often recognize this fact by endeavouring to restrain to the utmost even the necessary movements of breathing.

Remedies which Diminish Expectoration.

The natural method of diminishing expectoration is by the removal of the condition which occasions it. This means the cure of the chronic bronchitis, &c., of which the expectoration is simply one of the consequences. Sometimes, however, in chronic cases when the quantity of expectoration is excessive, one is inclined to ask can nothing be done to diminish its bulk. The best treatment would be the administration of acid tonics, of which a list is given on p. 841. Acids have an undoubted effect in "drying up" the secretion.

Atropine, the active principle of belladonna (see section on Drugs Acting on the Nervous System), also acts to some extent in the same direction. Anyone taking belladonna or atropine is certain to complain of an excessive dryness of the mouth and throat, due to the diminished secretion from the glands of the mucous membrane. For this purpose from the $\frac{1}{120}$th grain to $\frac{1}{80}$th grain of atropine, or 5 drops of tincture of belladonna, might be taken several times daily. It is to be observed, however, that atropine and belladonna also act upon the nerves of the respiratory organs, quieting them. The efforts to expel the expectoration would, therefore, be lessened, and there would be the risk of the material accumulating in and blocking the lungs. It would, therefore, be well to combine the atropine with a stimulant, such as ammonia or senega, in the hope that there would be diminished secretion but increased expulsive effort.

Remedies which Relieve Spasm of the Air-passages and Cough.

This class of remedies and that of expectorants are the most important so far as the respiratory system is concerned. We have already referred to the fact that a prominent feature of the smaller bronchial tubes is the layer of muscular fibre in their walls, by whose contraction the passage is very much narrowed if not obliterated. In such a condition existing to any extent in the lung there would be great difficulty of breathing, from the greater or less degree of closure of the tubes. Such a state of affairs exists in spasmodic asthma. The muscular layer contracts because of stimulation reaching it along nerves, and the irritation of the nerves ending in the spasm may arise in the lungs themselves, or may exist in some other organs. Thus acidity of the stomach or some congestive condition of the liver will sometimes determine an attack of asthma. Again the irritation may be applied to the nerve centre for respiration (p. 257), and may be due to the character of the circulating blood, as in gout and rheumatism. A similar kind of spasm is that by which the opening in the larynx—the chink of the glottis—is closed, such as occurs in child-crowing. The second kind of spasm it is

necessary to soothe is that which manifests itself chiefly in cough. Whooping-cough is essentially of a spasmodic character. In many instances, owing to the extreme irritability of the nerves of the air-passages, the slightest irritation, whether by breathing cold air, or the inhalation of dust, or irritation of the stomach, or irritation of the nose, as is often present in the form of polypus, is sufficient to set up a dry hacking cough. This is a kind of spasm also to be relieved by soothing remedies. The chief of such remedies are lobelia, stramonium, belladonna, hyoscyamus, tobacco, conium, as well as general sedatives like opium. It should not be forgotten, however, that the best remedy for spasm may often be some substance which may at first increase the spasm, such as ipecacuanha, by increasing the cough, but will speedily get rid of it by expelling the phlegm or other material whose stay in the air-passages is the cause of disturbance. Similarly an emetic may sometimes be the best remedy, by emptying the stomach and mechanically clearing the air-passages at the same time.

Lobelia.—The leaves and tops of *Lobelia inflata,* native to North America. The herb is also called Indian tobacco. Its preparations are:

Tincture of Lobelia,[1]............Dose, 10 to 30 drops.
Etherial Tincture of Lobelia,... ,, 10 to 30 drops.

Uses.—In large doses lobelia causes burning pain, vomiting, and purging, acting as an irritant poison, and great prostration, headache, and giddiness result, and, in poisonous doses, failure of the heart and breathing. The remedy for this state of things is strong stimulants after the stomach has been emptied. It is chiefly employed in spasmodic asthma, being given in 10-drop doses while the fit is on, repeated every ten minutes till sickness is produced. In bronchitis, with a tendency to spasm, it is given in 10-drop doses with ammonia, senega, or other expectorants.

Stramonium, or Thorn-apple (Plate XII.), is discussed on p. 900. Its chief use is for nervous asthma, for which it is employed by mixing 15 grains of the dried leaves, or 7 of the fibres of the dried root, with sage leaves or tobacco and smoking it in a pipe or cigarette, inhaling the smoke. The leaves of *Datura Tatula,* a plant of the same genus, may be used instead of those of *D. Stramonium.*

Belladonna, hyoscyamus, and tobacco are discussed in the section devoted to Drugs Acting on the Nervous System. The value and use of belladonna in whooping-cough have been referred to on p. 417.

Conium maculatum or Spotted Hemlock (Plate XI.) is used chiefly in the form of vapour as an inhalation to relieve cough in bronchitis, consumption, and whooping-cough (see p. 903).

Vapour of Hemlock (extract of hemlock 60 grains, solution of potash 1 drachm, water 10 drachms; mix.) Put 20 drops on a sponge in an inhaler containing hot water.

Nitrite of Amyl has been referred to as valuable in asthma on p. 837, and the inhalation of the fumes of nitre paper on p. 274.

Remedies for Cough have been stated at sufficient length on p. 284. One need only insist here on the fact that very frequently the best remedy for cough is some means which will loosen phlegm and permit of its ready expulsion, such as warm drinks, warm applications, and expectorants like ipecacuanha. The constant hacking exhausting cough, with little spit or none at all, demands, however, some soothing remedy. Inhalations of steam will help, and probably some actively soothing drug will be necessary, of which the best is one of the preparations of opium. (Refer to opium in the section relating to Drugs Acting on the Nervous System.)

Of popular remedies for cough, horehound (p. 882), marsh-mallow and colt's-foot are the chief.

Marsh-mallow (*Althæa officinalis,* natural order Malvaceæ) is a perennial herb, common to the greater part of Europe and naturalized in America, growing in marshy places near the sea. The root is chiefly used, but the leaves and flowers also. The root, collected in early spring or autumn, is dirty white externally and pure white within. It has a faint aromatic odour and a sweet mucilaginous taste. It is employed for its soothing effects on irritable inflamed surfaces. Poultices of the bruised root are employed to relieve inflammations of the skin. An ointment may be made by boiling the cut fresh leaves with lard for half an hour and then straining. In psoriasis of the hand it has proved effective. The ointment of the shops is used for irritable sores. In sore-throat marsh-mallow lozenges are exceedingly soothing. One kind of such confection is the *pâté de guimauve.* For irritable cough this or the syrup may be used. The syrup is made thus:—Of the dried and sliced root $1\frac{1}{2}$ ounces are steeped in 1 pint of cold water for twelve hours. The

[1] The American tincture is weaker; of it the dose is 30 to 120 drops.

liquor is then pressed out and strained through muslin. To the liquor twice its weight of sugar is added and the whole dissolved by a gentle heat. When the syrup is cold, add half a drachm of rectified spirit to each ounce. The dose is from a tea-spoonful to a table-spoonful.

Many varieties of mallow are used in a similar way.

Colt's-foot (*Tussilago farfara*, of the natural order Compositæ) is also a perennial herb, common in Europe, Asia, and America, growing in damp soil, in ditches, and along brooks. An infusion is made (1 ounce of dried leaves and flowers to 1 pint of hot water) for coughs and chronic bronchitis; and of it a tea-cupful may be taken at a time. The smoke of the burning root is inhaled in chest affections, and the root is also smoked in a pipe for lung affections.

Liquorice, Spanish-liquorice, the root and underground stem of *Glycyrrhiza glabra*, of the order Leguminosæ, is employed in cough and irritable conditions of the air-passages, because of its bland and soothing properties. It is also added in powder because of its sweetness to several preparations, such as the preparation of senna (p. 857). A fluid extract is prepared, and there is also the well-known dry extract, in sticks. It is often associated with linseed to yield a soothing drink for irritable states of the air-passages. Such a preparation is the infusion of linseed, made as follows:—

Linseed,...............................	160 grains.
Fresh liquorice root, sliced,....	60 grains.
Boiling water,......................	10 ounces.

Infuse 4 hours and strain. One to two ounces of this is a dose.

SECTION VI.—DRUGS WHICH ACT UPON THE SKIN.

Drugs which Increase the Amount of Sweat—Diaphoretics and Sudorifics:
- *Acetate of Ammonia;*
- *Dover's Powder—Ipecacuanha and Opium;*
- *Camphor and Antimony;*
- *Jaborandi and Pilocarpine.*

Remedies for Excessive Sweating:
- *Belladonna and Atropine*—Their Use in the Night-sweats of Consumption;
- *Oxide of Zinc;*
- *Acids and Acid Sponging.*

Drugs which Improve the Nutrition of the Skin:
- *Iron, Arsenic, &c.;*
- *Sassafras; Woody Nightshade (Dulcamara); Burdock; Rhus Toxicodendron (Poison Oak).*

There are a great many remedies applied to the skin to produce merely local effects, such as ointments, washes, &c., and others for the purpose of acting upon deeper organs, such as stimulating liniments, blisters, and so on. These remedies it is not our purpose to discuss here. They are considered in a later section on Remedies for External Application. Here we wish to note the chief remedies employed to act upon the skin as a whole. The skin, as we have seen, has two main functions (see Section XI. A. p. 306): first an excretory function, by removing water with a small portion of salts in solution; and second, and perhaps the more important function, that of regulating the temperature of the body. The excretory function is effected entirely by the glands of the skin, but their activity may be stimulated by nerves, or, without any nervous stimulation reaching them directly, they may be excited to more vigorous action by an increased flow of blood to them owing to dilatation of the blood-vessels of the skin. The regulation of the body heat, however, may be affected both by the activity of the glands and by the activity of the circulation, together, or by one apart from the other. Thus dilatation of the blood-vessels of the skin and an increased flow of blood in the skin might exist apart altogether from any increased activity of the glands, and there would be an increased loss of bodily heat from the exposure of a greater quantity of blood to the external air. On the other hand increased sweating might occur, owing to nervous excitement, even when the quantity of blood flowing in the skin was less than usual. We know the sudden outburst of sweating that occurs in some people with fear, even when the marked pallor of the skin indicates contracted blood-vessels, and how, when a person is rallying from a threatened faint, beads of perspiration stand upon the forehead in curious contrast to the paleness of the face. The functions of the skin, then, may be altered by remedies (1) which affect the circu-

lation in the skin, and (2) which act upon the glands. It appears that the glands may be acted upon in more ways than one. They are supplied with nerves, and there are some drugs, notably pilocarpine, which stimulate the nerve terminations in the cells of the glands and thus excite increased secretion, while atropine, the active principle of belladonna, has a reverse effect, paralysing the nerve terminations so that secretion is arrested. Other drugs excite not the nerve terminations in the glands, but certain parts of the central nervous system which are in communication with the glands. Thus in the upper part of the spinal cord there is believed to be a centre presiding over sweating, the exciting of which will cause an increase of sweating in the upper extremities, while a similar centre exists low down in the spinal cord, stimulation of which causes increase of sweating in the lower extremities. The condition of the blood affects these centres, exciting them if the oxygen of the blood be deficient; and nicotine, the active principle of tobacco, excites them also. Through these centres, by a reflex action (p. 86), impressions affecting sensory nerves throughout the body may affect the amount of sweating. In this way severe pain acts in causing sweating and sickness. It is also through these centres that mental emotions cause increase or diminution of the amount of perspiration.

Drugs which Increase the Amount of Sweat.

Drugs which increase the perspiration are called **diaphoretics** or **sudorifics**, according to the extent of the increase. Diaphoretics (Greek *diaphoreo*, to carry across) are drugs moderately increasing the sweat, and sudorifics (Latin *sudor*, sweat, and *facio*, I make) is the term applied to drugs with more powerful action, when the perspiration streams from the surface.

Heat is one of the simplest means of acting upon the skin to promote sweating. This it does by dilating the blood-vessels of the skin and increasing the activity of the circulation. Warm air, warm clothing, the warm bath, and warm spiced drinks, all these are well-known means of accomplishing the purpose sought. Alcohol has a similar effect, relaxing the blood-vessels of the skin and promoting a feeling of warmth, though actually cooling the skin by increasing the loss from the surface.

The chief sweating drugs are:—

Solution of Acetate of Ammonia (Mindererus' Spirit).
Dover's Powder (Ipecacuanha and Opium).
Camphor. Antimony. Pilocarpine.

Solution of Acetate of Ammonia (p. 843), when given internally, acts on the skin, if the body be kept warm, and on the kidney if the skin be kept cool. Its dose is from 2 to 6 tea-spoonfuls. It is one of the mildest and safest of sweating remedies, peculiarly suitable for children, used in fevers, those attended by rash, and feverish colds, and when fever is present from other causes, as in inflammation of the lungs. It soon makes the dry hot skin pleasantly moist. It is usefully combined with spirit of nitrous ether to act upon the kidneys (see next section). The drug acts apparently upon the cells of the sweat glands, as well as dilates the blood-vessels of the skin.

Dover's Powder, the compound powder of ipecacuanha and opium (see p. 852), is one of the most commonly used of sweating powders. Its dose for an adult is 10 grains; and it should not be given to children. Its effect in the early stage of cold-in-the-head, or influenza-cold is remarkable, if it be taken soon enough. It commonly dispels the dull headache, the pains in the bones, and the sickness, as if by magic. The person ought to take the powder, use a footbath, get into bed, and have a warm drink; and then the beneficial effects are speedily felt. Ipecacuanha itself acts upon the skin, and may be given as powder, or as the wine, to children; and opium alone, or any of its preparations, also increases sweating (see Section VIII.), but they are best given in combination, except in the case of children.

Camphor (see p. 850) and other aromatic substances increase the production of sweat. Camphor is specially employed in cases of catarrh or cold-in-the-head in 2 or 3 grain doses, or as the spirit of camphor and as vapour.

Antimony was at one time much used for this purpose in the form of James' Fever Powder (p. 853), but is little employed nowadays.

Pilocarpine is an alkaloid derived from the dried leaflets of *Pilocarpus pinnatifolius*, or *Jaborandi*, a plant found in South America. Of jaborandi there is an extract (dose: 2 to 10 grains), an infusion (dose: 1 to 2 fluid ounces), and a tincture (dose: $\frac{1}{2}$ to 1 tea-spoonful), and in America a fluid extract of pilocarpus is obtained (dose: 5 to 60 drops). Of the alkaloid pilocarpine itself the dose is $\frac{1}{20}$ to $\frac{1}{2}$ grain, as nitrate or muriate (hydrochlorate) of pilocarpine.

Uses.—If a dose of from $\frac{1}{20}$ to $\frac{1}{3}$ grain of the muriate of pilocarpine be injected under the skin of a person, it produces in a few minutes flushing of the face and breast, and sweat appears first

on the forehead and in the arm-pits and then over the whole body. Saliva is increased, the tear glands become more active, and the secretion of wax in the ears and of mucus in the throat and nostrils is increased. The gastric glands and intestinal glands are sometimes excited, and diarrhœa sometimes occurs; while the kidney is stimulated, and the flow of milk in the breast glands is sometimes, though not always, augmented. By irritation of the stomach it sometimes causes sickness and vomiting. The pulse is increased, and vision becomes indistinct by contraction of the pupil. It produces, sometimes even in small doses such as that named, unpleasant symptoms, such as palpitation, giddiness, retention of urine and strangury, and collapse, and it brings on in women the monthly flow. These bad effects can be arrested by the use of atropine. It is chiefly used in dropsy to promote removal of the accumulation of water, which it is well fitted to do, since in a few hours the body may lose eight pounds weight from the combined sweating and flow of saliva. It is found useful in arresting convulsions dependent upon kidney disease. The enormous loss of water from the body it occasions has been found to promote the cure of pleurisy with effusion by withdrawing fluid from the chest-cavity. In asthma and bronchitis with much expectoration it has yielded benefit, and it has cured a persistent case of hiccough which resisted all other treatment. It has also been employed to promote sweating in fevers and feverish colds, and in itching skin diseases; and it has been employed, but without much success, in eye diseases, specially in separation of the retina, from the notion that it might remove the fluid beneath the retina which is the cause of the detachment. Pilocarpine is an antidote to poisoning by belladonna and *vice versa.*

Remedies for Excessive Sweating.

The chief remedies for excessive sweating, that is drugs which diminish the secretion of sweat, are belladonna, and its active principle atropine, and zinc.

Belladonna and **Atropine** are discussed in Section VIII. It is well to note here, however, the powerful effect they have in diminishing sweating. When belladonna is taken internally the throat and skin are both dry. The effect upon both is due to a paralysing influence upon the secreting cells of the glands. The secretion of saliva can be completely arrested by the drug, owing to the paralysis of the cells. It is, therefore, a most valuable drug whenever any such effect is desired. Thus in the night-sweats of consumption a pill of the extract of belladonna, $\frac{1}{2}$ to 1 grain, or $\frac{1}{200}$ grain of atropine is often sufficient. The excessive sweating of acute rheumatic fever may be similarly arrested. When the sweating complained of affects only one part of the body, say arm-pits, feet, &c., the remedy may be employed as a paint to the part in the form of the extract made somewhat thin with glycerine, or the tincture may be rubbed in as a lotion. It is a similar action which makes belladonna very useful for diminishing or arresting the flow of milk from the breast. It should be applied as a paint of the extract, and the breast covered with a square of lint, a piece being cut out of the centre for the nipple.

Zinc Salts, specially the oxide of zinc, 1 to 3 grains in pill, are also valuable in excessive sweating. A pill of

2 grains oxide of zinc,
$\frac{1}{8}$ grain belladonna extract, and
$\frac{1}{4}$ grain extract of nux vomica,

given at bed-time, is likely to be sufficient to check the night-sweats of consumption.

Acids, especially the dilute aromatic sulphuric acid in doses of 10–20 drops in water, are employed successfully to check the sweats of consumption. Any of the dilute acids mentioned on p. 841, freely diluted with water, and used to sponge the surface of the body, will often effectually control excessive perspiration.

Drugs which Improve the Nutrition of the Skin.

There are numerous drugs which act upon the skin, not in any obvious manner, and without so markedly influencing the perspiration as the two classes of drugs which we have considered already in this section, but by gradually improving the nutrition of the skin. They are such drugs as we have considered in Section I., which imperceptibly modify the chemical changes going on in the tissues, and ultimately induce healthier action, namely:—Iron (p. 817), arsenic (p. 823), sulphur (p. 827), sarsaparilla (p. 828), guaiacum (p. 828), mezereum (p. 829). The last four act as stimulants to the circulation in the skin, and thereby also increase the action of the glands. Senega, although it is chiefly used as a stimulant to the air-passages (p. 880), has a like effect upon the skin, thereby promoting the action of the skin. Serpentary (p. 841) may be grouped along with these for its stimulating effect upon the circulation in the small blood-vessels.

Sassafras, the dried root of the sassafras

tree (*Sassafras officinalis*), growing in the United States and Canada, is sometimes used in cases of chronic skin diseases, such as those for which sarsaparilla, guaiacum, &c., are employed. It is a stimulant to the skin, and was formerly used in chronic diseases of the skin and in syphilis, the popular belief being that it "helped to purify the blood." It increases also the action of the kidneys.

Dulcamara, Woody Nightshade, or Bittersweet, the dried young branches of *Solanum Dulcamara*, is another remedy which improves the condition of the skin, and has long been used as a popular remedy for scaly diseases of the skin, psoriasis, eczema, acne, and others. It has also been employed in chronic bronchitis and other lung affections. It can act, however, as a poison, slowing the heart and breathing, and causing death with convulsions. Of the infusion of dulcamara the dose is 1 to 2 fluid ounces. The infusion is made with 1 ounce bruised dulcamara and 10 ounces boiling water infused one hour and strained.

Burdock, the root of *Lappa officinalis*, of the Compositæ order, has long had a popular reputation for the cure of chronic skin diseases, as well as for rheumatism, gout, scrofula, chest affections, &c. It is used both as an internal medicine, and for outward application. For the former a decoction is made by boiling 2 ounces fresh-bruised root in 3 pints of water down to 2 pints. A pint of this should be taken daily. Another preparation is made by adding 1 pound of ground burdock seed to a gallon of whisky, letting it stand for two weeks, and then decanting. Of this 2 or 3 tea-spoonfuls are taken after meals. The fresh leaves bruised, the juice from fresh leaves, and lotions made by boiling the leaves or root with oil, are used for ulcers, wounds, and various other skin affections.

Rhus Toxicodendron—Poison Oak, Poison Ivy—is a plant belonging to the natural order Terebinthaceæ, to which also the **Common Sumach** (*Rhus glabra*) and the **Sweet Sumach** (*Rhus aromatica*) belong. It is indigenous to Canada and the United States. The emanations of the living plant and the juice of the fresh leaves produce an eruption on the skin attended by itching, swelling, pain, and fever. For this lime-water or lead lotion is a good application. A tincture is prepared of which the dose is 1 to 5 drops in water thrice daily. It has been recommended in chronic skin affections, in rheumatism, in incontinence of urine due to weakness of the bladder, and in paralysis dependent upon concussion of the spine. The tincture is known by the author to have been taken internally by a person who was very much annoyed by the growth of warts on the fingers, and with perfect success, the warts completely disappearing after some time. There seemed little doubt that the drugs exerted some special action on the nutrition of the skin. It is for this reason he deems it proper to give the remedy a place in this section.

The common and the sweet sumach have both been used for their astringent properties as gargle, and for application to wounds, and also internally as a tonic to the bladder. An infusion of leaves or bark, 1 oz. to 20 of water, may be used.

SECTION VII.—DRUGS WHICH ACT UPON THE KIDNEYS, BLADDER, AND GENERATIVE ORGANS.

Drugs which Increase the Quantity of Urine—Diuretics:
Water and Watery Drinks;
Salts of Potash and Soda;
Ammonia; Digitalis; Squill;
Sweet Spirit of Nitre;
Broom-tops; Juniper; Copaiba; Hops; Pareira; Buchu; Bearberry;
Chimaphila; Dandelion.

Remedies which Soothe the Kidneys.

Drugs which Stimulate the Bladder.

Drugs which Allay Irritability of the Bladder.

Drugs which Act on the Generative Organs:
Pennyroyal, Savin, and Rue;
Black Snake-root (Cimicifuga); Blue Cohosh (Caulophyllum);
Pulsatilla and Beberine.

DRUGS WHICH ACT UPON THE KIDNEYS.

The chief object desired from drugs, given to act upon the kidney, is to increase the flow of urine. This result may be sought because the flow is scanty, or because of some disease of the

kidney or bladder, or, while the urinary organs are healthy, they may be stimulated in order to effect the removal of some dropsical accumulation of fluid in some part of the body, or the kidney may be stimulated in conditions of fever in order to aid in diminishing the fever, and to sweep out of the body waste materials which the fever has produced. Drugs which have the effect of increasing the flow of urine are called **diuretics** (Greek, *dia*, through, and *oureo*, I pass water). It is necessary, however, to observe, that drugs which increase the activity of the kidney, and increase the quantity of water produced by them, are not always the appropriate remedy when there is a scanty flow of urine. A person, for example, may pass very little water at a time, or may be unable to pass water at all. It would be a very great mistake to give that person a dose of spirits of nitre, as is common, or gin, or some similar remedy, for the fault may not exist in the kidneys at all, which may be doing their work quite satisfactorily; the fault may be in the bladder which has lost the power to expel the urine, or which is prevented expelling the urine by some spasmodic condition of the neck of the bladder, or some inflammatory swelling which obstructs the flow of urine. Under these circumstances to give medicine which would increase the flow of urine into an already full bladder, would only be greatly to add to the uneasiness, discomfort, and pain which the person is suffering. What is evidently needed is some means of emptying the bladder. The relation between the kidney and bladder is set forth in Part I., Section X. A. p. 288, where it is explained that the urine, secreted in the kidneys, is passed down the ureters, a fine tube leading from each kidney to the bladder, and that the urine flows into the bladder constantly, but drop by drop. When the bladder is full, owing to a nervous action the muscle guarding the neck is relaxed, and the urine expelled by the contraction of the muscular walls of the bladder (see p. 294). The distinction then between the secretion of urine by the kidney and its expulsion by the bladder must never be forgotten. It is only in the cases where it is desired to act upon the kidney that diuretics are given.

Drugs which Increase the Quantity of Urine.

The following is a list of the chief drugs which increase the quantity of urine:—

Water in large quantities.
Aerated waters.
Acetate, citrate, nitrate, and bicarbonate of potash.
Bicarbonate and phosphate of soda.
Citrate and carbonate of lithia.
Ammonia, Digitalis, Squill, } By strengthening the heart.
Nitrous ether.
Broom-tops.
Juniper.
Copaiba.
Hops.
Pareira.
Buchu.

Of water and aerated waters it is not necessary to say much. All watery drinks increase the quantity of urine, because the water is absorbed from the stomach and passes into the blood, and is speedily excreted by the kidneys. If one drinks, while fasting, several glasses of spring water, one after the other, at intervals of 15 or 20 minutes, after the second or third glass, water will be passed less coloured than usual and in quantity very nearly equal to the first glass. If one goes on drinking, the urine will keep pace with the water imbibed, and after many glasses will be little different from spring water. This clearly would produce a flushing-out action on the kidneys and bladder, and would also remove much waste material from the body, being beneficial in gouty conditions and as a preventive of gravel. In many cases of inflammation of the kidney, where one wishes to pass a larger quantity of water through the kidney without irritation, water and watery drinks, milk with aerated waters, are very suitable.

The saline substances in the above list—acetate, citrate, &c., of potash, and the salts of soda and lithia—have been noted elsewhere (pp. 818, 819). These are capable of acting both on the bowels and the kidneys, at least the salts of soda and potash are, and very often the relief they produce by their action on the bowels has a very beneficial effect on the kidney. In feverish conditions they are useful. The salts of potash are commonly given along with the sweet spirit of nitre in dropsy; they and the soda salts are commonly used when it is desired to diminish the acidity of the urine, and lithia is specially given for such purposes in gouty and rheumatic conditions.

Ammonia, digitalis, and squill all act upon the kidney indirectly by their tonic action upon the heart and blood-vessels. Whenever dropsy with scanty, high-coloured urine is the consequence of feeble and irregular heart, digitalis is the remedy to be used (see p. 832), though it is usual also to combine it with the aromatic

spirit of ammonia or carbonate of ammonia (p. 843), to aid the stimulating action on the heart. When digitalis fails, the addition of squill (p. 833) helps to produce the desired effect, after the bowels have been relieved by blue-pill.

Spirit of Nitrous Ether—Sweet Spirit of Nitre—the dose of which is ½ to 2 tea-spoonfuls, is one of the most commonly used of remedies for increasing the quantity of urine. It relaxes the smaller blood-vessels of the skin and kidneys, thus allows a freer flow of blood through them, and causes a corresponding increase in the urine and sweat. It is familiarly used in feverish states, for this action that has been described results in cooling the body. It should not be used in acute disease of the kidney, because of its effect in promoting a fuller supply of blood to the kidney.

Broom-tops (*Scoparius*), the fresh and dried tops of the shrub *Sarothamnus scoparius*, abundant in Great Britain. It belongs to the leguminous order of plants, to which the pea and bean also belong. It contains a poisonous alkaloid, **spartein**, and another principle called **scoparin**. Its preparations are:—

	DOSE.
Decoction of Broom-tops, ...	1 to 3 fluid ounces (2 to 6 table-spoonfuls).
(1 oz. dry tops, 1 pint water; boil 10 minutes and strain.)	
Juice of Broom-tops, ...	1 to 2 tea-spoonfuls.

Broom-tops are used only for their action on the kidneys. They are employed in cases of dropsy due to chronic disease of the kidney, usually along with digitalis or acetate of potash. The active principles of the drug appear to excite the secreting cells of the kidney, and on this account, while it is useful in chronic disease, it is hurtful in acute disease of the kidney, where soothing treatment is desired.

Juniper, the fruit of *Juniperus communis*, a shrub 4 to 6 feet high, whose fruit—juniper berries—is berry-like in appearance. Its preparations are:—

	DOSE.
Oil of Juniper (distilled from the fruit),.........................	1 to 4 drops.
Spirit of Juniper,....................	30 to 60 ,,
Compound Spirit of Juniper,....	2 to 4 tea-spoonfuls.
(Contains oils of juniper fennel and caraway, and alcohol.)	

Uses.—Juniper is contained in gin and hollands, and it is because of its virtues that these are recommended to increase the quantity of water. Its action resembles that of turpentine. It acts as a stimulant to the stomach, expels wind, and relieves spasm. It directly stimulates the kidney, increasing the urine, but if given in excessive doses causes inflammation and strangury.

Copaiba (see p. 881) is sometimes used in dropsy, dependent upon affection of the liver or heart; but its irritating properties render it liable to do harm if the kidneys are diseased. Its chief use is for catarrhal conditions of the bladder and urinary outlet.

Hops act slightly upon the kidneys, and beer possesses such a property on account of their presence. Besides the infusion mentioned on p. 841, there is a tincture, of which the dose is ½ to 2 tea-spoonfuls.

Pareira Root—Pareira Brava—the root of *Chondodendron tomentosum*, a woody climber of Brazil and Peru, known as *Cissampelos abutua*. Its preparations are:—

Powdered Pareira Root, ...	Dose, 30 to 60 grains.
Decoction of Pareira,................	,, 1 to 2 ounces.
(Sliced root 1½ oz., water 1 pint; boil 15 minutes, strain. Add water to make a pint.)	
Infusion of Pareira, ...	Dose, 1 to 2 ounces.
(1 oz. bruised root, 1 pint boiling water; infuse 2 hours.)	
Extract of Pareira, ...	Dose, 10 to 20 grains.
Liquid Extract of Pareira,	,, ½ to 2 tea-spoonfuls.

Uses.—Pareira is a bitter tonic. It stimulates the kidney, increasing the flow of urine. It is also a stimulant to the mucous lining of the urinary passages; and it is in chronic catarrh of the bladder that it is most commonly used, when it promotes healing and lessens the discharge.

Buchu Leaves are the dried leaves of *Barosma betulina*, *crenulata*, and *serratifolia*, three shrubs belonging to the order Rutaceæ, indigenous to Cape Colony. Its preparations are:—

	DOSE.
Infusion of Buchu,...................	1 to 2 ounces.
(Infuse 1 oz. of the leaves for 1 hour in 20 ozs. boiling water and strain.)	
Tincture of Buchu, ...	1 to 2 tea-spoonfuls.
Liquid Extract of Buchu, ...	20 to 45 drops.

Buchu is used chiefly as infusion, and for the same purpose as pareira root. It is a tonic, exciting a feeling of warmth in the stomach, quickens appetite and digestion, and is used in South Africa in doses of 20 grains of the powdered leaves for similar effects on the bowels in cases of diarrhœa and dysentery. It acts on the kidneys and bladder as a stimulant, and is often used with infusion of bearberry leaves (*uva ursi*).

Bearberry Leaves, the dried leaves of *Arctostaphylos uva ursi*, a trailing evergreen shrub of the order Ericaceæ, growing in most

parts of Europe, Northern Asia, and North America. Its preparations are:—

Infusion of Uva Ursi,............ (1 oz. leaves, 20 ozs. boiling water, infuse 2 hours and strain.)	Dose, 1 to 2 ounces.
Fluid Extract of Uva Ursi,......	„ 30 to 60 drops.

Bearberry leaves contain tannic and gallic acids, and are therefore astringent. It also contains a principle called **arbutin**, to which its effects on the kidneys and bladder appear to be due. It increases the flow of urine, and stimulates the urinary passages; but in too large doses it occasions vomiting and purging. It is in chronic diseases of the kidney and bladder it is most useful. By its astringent effect on the bladder it frequently relieves pain and irritation due to excessive sensibility of the bladder. It has also been used in chronic bronchitis, and in chronic discharges from the bowels and womb, and in bleeding from the womb.

Triticum Repens or **Couch-grass,** a common weed, with a long jointed root-stock, is used to yield a decoction for cases of irritation of the urinary passages. The root-stock is the part employed; 2 to 4 ounces of it are bruised and mixed with 2 pints of water. The mixture is boiled till it is reduced to 1 pint, and then drained. A wine-glassful may be taken frequently. It increases the flow of urine, and soothes the urinary passages, and was supposed to aid the removal of gravel from the bladder.

Alchemilla arvensis (Parsley Breakstone) is employed for the same purposes as the above; of the flower-heads 1 oz. is boiled with 20 of water for ten minutes, and strained. A wine-glassful, thrice daily, is taken.

Chimaphila is a remedy used in America, and known under the name of Pipsissewa, Prince's Pine, and Wintergreen. The plant is the *Chimaphila umbellata*, of the Ericaceæ order, and the leaves are used as powder, of which the dose is 30 to 60 grains, or to yield a fluid extract, of which the dose is 1 teaspoonful.

It contains tannin, and is astringent. It is also a stimulant, the fresh bruised leaves reddening the skin. It resembles bearberry in its effects, and is used popularly in America for kidney diseases, as uva ursi is employed, and for rheumatism, both internally, and externally as a poultice of the leaves to the painful joints. It is said, also, to be useful in scrofulous disease of glands and skin.

Dandelion also acts upon the kidneys (see p. 858).

Remedies which Soothe the Kidneys.

Remedies which soothe the kidneys will be such as will withdraw blood from them, and so lessen the activity of the circulation through them, and also such as will directly act upon the secreting cells of the uriniferous tubules (see p. 290) and diminish their activity. Nothing will more quickly or effectively accomplish the former result than drugs which act briskly upon the skin and bowels, causing free sweating and purging. It has already several times been pointed out that the skin and kidneys work together, the increased activity of one being accompanied by diminished activity of the other. If the skin, therefore, be kept warm and sweating, for example by a dry external heat, the activity of the kidney will be lessened and the quantity of the urine diminished. Such a result is quickly obtained by a Turkish bath. Similarly a mustard foot-bath, or a large mustard poultice to the loins, by drawing the blood to the surface, will relieve the kidneys. These are always the appropriate measures to be taken in acute disease of the kidneys. Then if the skin is kept warm, acetate of ammonia and spirit of nitrous ether will encourage sweating; and in very urgent cases pilocarpine (p. 887) will induce copious perspiration, unburdening the kidneys. Simultaneously with such remedies, the administration of drugs which promote the removal of water by the bowels, such as the compound powder of jalap (p. 861), compound colocynth pill (p. 860), or blue-pill, followed by double-strong seidlitz powder, will greatly aid in relieving the kidneys and reducing inflammatory disturbance.

It is not so easy to say by what means the cells of the kidney may be directly acted upon in order that their secretory activity may be lessened. The author believes that belladonna and its active principle atropine have such an effect (see Section VIII.), and perhaps ergot (p. 835), by contracting the blood-vessels diminishes the supply of blood to the kidneys, and consequently lessens their activity. In acute inflammatory affections, relief to the kidney is, however, to be obtained by the other measures described.

DRUGS WHICH ACT ON THE BLADDER.

Drugs which Stimulate the Bladder.

These drugs have already been stated in preceding paragraphs—copaiba and cubebs (p. 881), pareira brava, buchu, and bearberry (p. 891).

Strychnine (see p. 895) exercises a tonic influence on the muscular walls of the bladder, and may be of value where there is weakness of expulsive power. The bladder may be excited to empty itself by the application of a cold wet sponge close up between the legs. The effect of mental impressions in setting agoing the nervous action that causes emptying of the bladder is well seen by the sound of falling water tending to produce evacuation. An old surgeon, Boerhaave, used to help a patient, unable to pass water, by making an attendant pour water from a height into a basin in a neighbouring room, so that the sound was heard by the patient, ignorant of the little trick played on him, and started the flow.

Remedies which Allay Irritability of the Bladder.

Heat is a powerful means of soothing the bladder, applied either externally as a hot sitz bath, or as a hot sponge or poultice, or taken internally as a hot bland drink such as barley water or linseed tea. Opium, hyoscyamus, and belladonna (all discussed in Section VIII.) are the chief drugs employed; and they are best given in the form of suppositories. But it must not be forgotten that excessive acidity of the urine or other condition may be the cause of the irritability; and the rectifying of this condition would be necessary to permanent relief.

Remedies that Act on the Generative Organs.

It is not desirable to do more than notice a few of the drugs employed to act upon these organs, specially upon the womb.

Many drugs are employed to excite the womb in order to promote the flow of the monthly discharge when it has been arrested or has failed to appear. Of these the one in common use is **Pennyroyal,** the leaves and tops of *Mentha Pulegium*, or *Hedeoma*, the American pennyroyal. It is used as a hot infusion, ½ oz. to 1 pint of water infused for half an hour, and given in half a wine-glassful doses at repeated intervals. **Savin Tops,** the fresh and dried tops of *Juniperus Sabina*, and **Rue** are sometimes employed for a like purpose, as also are drastic purgatives. These are mentioned only that a warning against their use may be given. They produce effects by the intense irritation of stomach and bowels which they set up, irritation which has often proved fatal.

The American **Black Snake-root** (*Cimicifuga racemosa*, or *Actæa racemosa*) is very often used as a uterine stimulant. It has proved useful also in rheumatism, neuralgia, sick headache, and lumbago, in doses of 15 to 60 drops of the tincture, or 5 drops every hour. A decoction is prepared by boiling 1 oz. in 20 ozs. water, of which 1 oz. is a dose. A liquid extract is prepared of which the dose is 3 to 30 drops. In too large doses it produces sickness, vomiting, and depression. In bronchitis it has been used to aid expulsion of matter from the air-tubes.

Blue Cohosh (*Caulophyllum—Pappoose-root—Squaw-root—Blueberry-root*), of the order Berberidaceæ, is much used in America as a tonic and stimulant to the womb. A decoction is made with 1 oz. root to 20 ozs. water, of which 1 oz. is the dose.

Pulsatilla, the flowering herb of *Anemone Pulsatilla* or *Pasque-flower*, is used in similar circumstances. An infusion of 60 grains of the fresh plant in 3 ozs. of water is given during the day in divided doses, and a tincture is prepared of which 1 to 5 drops are given several times daily.

Of the drugs used to control bleeding from the womb, **Ergot** is the chief (see p. 835).

Sulphate of Beberine, prepared from the dried bark of the greenheart tree, *Nectandra Rodiœi*, called Bebeeru bark and imported from British Guiana, has been found useful in excessive discharge, given in 4-grain doses often repeated. It has also been employed as a substitute for quinine in neuralgia.

SECTION VIII.—DRUGS WHICH ACT UPON THE NERVOUS SYSTEM.

Nerve Tonics and Stimulants:
Their Use in the Treatment of Nervousness and Nervous Debility;
Nux Vomica and Strychnine;
Caffein (coffee);
Phosphorus;
Salts of Iron, Silver, and Zinc.

Drugs which Lessen Sensibility and Relieve Pain and Spasm:
Opium and its Active Principle Morphia;
Belladonna and its Active Principle Atropia;
Hyoscyamus and Stramonium;
Indian Hemp (Hashish—Cannabis Indica); and Calabar Bean;
Hemlock (Conium maculatum); Curare or Woorari; Yellow Jasmine (Gelsemium); and Cocaine.
Antipyrin and Phenacetin—Their Use for Headache and Neuralgia.

Drugs which Procure Sleep:
Opium and its Preparations;
Chloral Hydrate and Croton Chloral;
Bromide of Potassium;
Paraldehyd and Urethane;
Sulphonal; Chloralamid; Chlorobrom.

Drugs which Destroy Consciousness (Anæsthetics):
Chloroform and Ether;
Nitrous Oxide or Laughing Gas;
Bichloride of Methylene;
Bichloride of Ethidene;
Bromide of Ethyl; Tetrachloride of Carbon.

If any one who turns to this section will first of all read Section V. of Part I. (p. 84), he will be able to realize what a complicated problem it is to determine by what means the nervous system may be influenced in various directions. One must remember that the nervous system is the link which binds all the other systems together, it is through it that all the organs of the body are kept working together in harmony and sympathy, it is by means of it that delicate adjustments are effected to maintain the balance of power among the bodily organs. Again, it is by means of the nervous system that the relations between the body and the external world are recognized and maintained. Finally, it is the nervous system that is the seat of those higher powers of judgment, reason, imagination, volition, which distinguish the intelligent self-conscious being, and raise him above the level of the automatic machine. Now, one can hardly ask, "What drugs act upon the nervous system?" in view of such considerations, without realizing what an enormous field a full answer to the question would cover. Take a common illustration. A person suffers from pain, say neuralgia of the face, and we shall suppose there is apparently nothing to account for it, and no appearance of anything to suggest that the person is suffering at all—no swelling, nor redness, no decaying tooth, no inflamed ear. It is a pure nerve pain, a sensory nerve is in a state of irritation or agitation for no known reason. What is desired is some remedy which shall diminish the excitability of that particular nerve, which shall soothe it, quiet it down, and so cause the pain to cease. One may apply cold to the part, or heat to the part, or an electric current to the painful nerve; but suppose all these *local* means fail, and a drug requires to be given. It is evident that it is impossible to give a medicine which will single out that one excitable nerve, and lower its sensibility without acting on any other part of the nervous system. The drug that is taken passes into the blood before it can reach the affected part, and it reaches every other part of the nervous system, every other nerve, every part of the spinal cord and brain, and indeed every other part of the body to the same extent that it reaches the part affected with pain. It may so lower the sensibility of this particular nerve that the pain ceases, but it is plain it must have some effect upon other nerves also and other parts of the nervous system. So commanding may have been the pain, that, when it ceases, the person is aware only of its cessation, and thinks of nothing but of the relief experienced, although many other marked effects may have been produced. The commonest of all remedies, in such circumstances, is opium or morphia. But that

drug also acts upon the skin to cause sweating, upon mucous membranes, causing diminution of their secretion, so that there is dry mouth and throat and constipated bowels. It deranges the digestion. It acts upon the brain, at first stimulating it, so that soon the person enjoys a period of delicious exhilaration, is lively, and talkative, and imaginative, and so on. No better illustration could be found of the fact that it is impossible to limit the action of a drug, and that the exceedingly complex nature of the nervous system makes it still more difficult to define the exact nature of the action of drugs upon it. In the following classification of medicines, then, it must be understood that the drugs are classified according to the chief of the actions they produce, or according to the chief purpose for which they are employed; and it is not to be supposed that they produce the one particular effect and none other. Many of the drugs to be considered might appear under each of the different headings, producing as they do a variety of effects, according to the dose given.

Nerve Tonics and Stimulants.

The Uses of Nerve Tonics in Nervousness and Nervous Debility.—Nerve tonics and stimulants are drugs which improve the nutrition of the nervous substance, and so exercise a bracing and strengthening effect upon the nervous system. They are employed in the treatment of many nervous diseases, such diseases specially as are included under such general and vague terms as "nervousness" and "nervous depression." When, through overwork, great physical and mental strain, and so on, the general health has become impaired, the nervous system necessarily shares in the ill health. Under these circumstances certain symptoms may arise, referred to the nervous system, which need not imply any organic disease, but indicate only lessening of the usual activity of the nervous system, or some perversion of activity, simply due to the lowered nutrition of the nervous system and its exhaustion. Among such symptoms are headache, sleeplessness, irritability of temper, lessened power of mental work, and many others of a like kind. Then the symptoms which popularly are associated with "nervousness," such as unusual timidity, readiness in being startled, tendency to emotional disturbance, are common in exhausted conditions of the nervous system, for the irritability or excitability of nervous substance always rapidly becomes increased by exhaustion. Similar symptoms may arise suddenly as the result of a shock, whether physical or mental, implying perverted action of the nervous system. It is in such conditions that tonic treatment is necessary. Now, such tonic treatment will be, in the first place, general. That is, attention will require to be directed to improving the general health by appropriate food, by securing regularity of habits and regularity of the bowels, by change of air and scene, by cheerful occupation and surroundings, and by ordinary tonic remedies. All the usual remedies for improving the nutrition of the body are applicable in such cases: cod-liver oil (p. 877), iron (p. 817), arsenic (p. 822), phosphorus (p. 826), and zinc (p. 870), are those in common use; more rarely silver salts (p. 870) and copper (p. 869) have been employed. It is seldom one or other of these drugs is given alone, usually they are combined; such as, iron and arsenic, zinc and phosphorus, and almost invariably nux vomica or its active principle strychnine is added to the combination (see below). It may be added that, in the author's opinion, there are many such cases in which no remedy acts so quickly or satisfactorily as the constant galvanic current applied to the head and spine. It seems to him to be specially useful in such cases as have arisen from sudden shock, or where prolonged depressed nutrition has induced perverted action.

If we note the use of the iodide of potassium (see p. 825) in nervous diseases, we shall have grouped together the chief drugs employed to affect the nutrition of the nervous system. It is specially used for dispersing overgrowths of connective tissue which, by their pressure on the essential nerve elements, may be the cause of the nervous symptoms.

Nux Vomica and Strychnine.—The *Strychnos nux vomica*, or Koochla tree, is a tree belonging to the natural order Loganiaceæ, common in many parts of Hindostan, also found in Northern Australia, and imported from the East Indies. Its fruit is a globular, smooth, orange-coloured berry, about two inches in diameter, which contains about five seeds. It is the seeds that are used in medicine. A common name for them is *Poison-nut* or *Quaker-buttons.* Nux vomica is bitter; and all parts of the plant are so, probably also poisonous. The bark has been used to adulterate Angostura bark (see p. 840). The seeds are disc-shaped, about an inch in diameter, convex on one side or nearly flat, concave on the other, grayish in colour and

silky. The chief constituents are two alkaloids, **strychnine** and **brucine**, the former of which is present to the extent of $\frac{1}{4}$ to $\frac{1}{2}$ per cent, and the latter $\frac{1}{10}$th to $\frac{1}{2}$ per cent. The **bean of St. Ignatius** is the seed of *Strychnos Ignatii*, found in the Philippine Islands. It also contains strychnine and brucine.

The preparations of nux vomica are as follows:—

	Dose.
Powdered Nux Vomica,............	2 to 5 grains.
Extract of Nux Vomica, ...	$\frac{1}{4}$ to 1 ,,
Tincture of Nux Vomica, ...	5 to 20 drops.
Strychnine, ...	$\frac{1}{30}$ to $\frac{1}{12}$ grain.
Liquor Strychniæ,..................	4 to 8 drops.
Citrate of Iron and Strychnine,	1 to 3 grains.
Citrate of Iron, Quinine, and Strychnine, ...	1 to 3 ,,
Easton's Syrup—Syrup of Iron, Quinine, and Strychnine,.......	$\frac{1}{2}$ to 1 tea-spoonful.

(Each tea-spoonful contains 1 grain phosphate of iron, 1 grain phosphate of quinine, and $\frac{1}{32}$ grain of strychnine.)

Actions and Uses.—Nux vomica and strychnine have an intensely and persistently bitter taste, and are useful as simple vegetable bitters. They are often added to stomachic tonics, such as are described on p. 841, both acid and alkaline, the tincture of nux vomica being added to the alkaline, and the liquor strychniæ to the acid tonics. The special effect of the drug is to increase markedly the excitability of the spinal cord, so that the slightest impression upon the body, communicated by eye, ear, or skin, causes by reflex action marked muscular movements. Thus a person under the influence of the drug will start violently at the slightest sound, or touch; if he sees a carriage coming towards him, as he crosses a street, his muscles may suddenly stiffen up so that he comes to a dead stop and cannot move for an instant. If excessive doses are given, the slightest impression upon any of the senses causes violent muscular spasms over the whole body, convulsions indeed; the teeth and hands are clenched, and such violent spasm of the respiratory muscles that the breathing is arrested. Death takes place by exhaustion and suffocation. These results are not sought for, of course, in medicine. It is a gentle stimulation that is desired, which makes itself evident in increased strength, greater activity, more mental power and spirit, increased sensibility of touch, sight, taste, hearing, and sense in general. The drug acts also on the bowel, increasing the peristaltic movement. Because of these various effects the drug is used as a tonic in weak digestion, and in dyspepsia as the result of excess in alcohol, the tincture of nux vomica or liquor strychniæ being the form for administration. It is also combined with purgatives to exert a tonic influence on the bowel, the extract of nux vomica being suitable, $\frac{1}{2}$ to 1 grain, with, for example, $\frac{1}{8}$ grain podophyllin and $\frac{1}{4}$ grain aloin. In many forms of nervous affection it is useful; in nervous depression in pill, 1 grain of extract with $\frac{1}{8}$ grain phosphide of zinc, or $\frac{1}{32}$ grain of phosphorus. It may be given with iron and arsenic, as 3 grains of Blaud's pill, $\frac{1}{60}$ grain of arsenious acid and $\frac{1}{2}$ grain extract of nux vomica. It is used in cases of paralysis, and in such cases small doses must be begun with, as the patient is usually easily affected by it. Specially does benefit arise from its use in paralysis following diphtheria. It tends to accumulate in the system; but persons quickly get used to the drug, so that one should begin with a small dose, which may then be gradually increased till full doses are being taken. This is always advisable, as many persons are unusually susceptible to its influence. It is employed for sexual impotence. Poisoning by strychnine is met by chloral hydrate and morphia, and strychnine is itself used as an antidote to poisoning by these latter drugs.

Caffein, the active principle of tea and coffee (p. 654), is used in medicine in doses of 1 to 5 grains. There is a citrate of caffein of which the dose is also 1 to 5 grains, and an *effervescing* citrate of caffein is prepared of which the dose is a tea-spoonful. The action of caffein, taken as such, or as coffee, is at first to stimulate the brain and spinal cord, as well as the pulse and breathing. Large doses have a poisonous effect, depressing the heart and breathing, making the pulse irregular; and it may also act as an irritant to stomach and bowels. In the lower animals it produces convulsions like those due to strychnia, and causes death. It is used in medicine as a nerve stimulant in cases of fatigue, and specially for megrim or nervous headache, for which it is very useful, but not so certain in its results as antipyrin (p. 821). Its stimulating action on digestion is marked with some people; in others it rather arrests digestion. It has also an effect upon the kidneys, exciting increased flow of urine.

Drugs which Lessen Sensibility and Relieve Pain and Spasm.

The drugs to be noted under this head are those which diminish the sensitiveness of the nerves of sense, so that they receive impressions less readily. They are dulled or blunted so to

speak. Some of them, such as conium, cocaine, veratrine, aconitia, when directly applied to the skin over a painful part, will so lower the sensibility of the nerves of that part of the skin that it no longer perceives sensations of touch, or heat, or even pain. This effect is called local **anæsthesia** (Greek *an*, without, and *aisthēsis*, sensibility), and the substance an anæsthetic. Prolonged cold will produce such an effect; we all know how numb a part long exposed to the cold becomes, and how extreme cold blunts all the perceptions. Any substance will produce extreme cold which, when placed on the skin freely exposed to the air, rapidly evaporates, and will, therefore, act as a local anæsthetic. Many lotions applied to the skin to relieve pain are composed of such substances—chloroform, ether, &c. A spray of ether directed on a part of the skin will by its rapid evaporation cool the surface down to the freezing point, and then a deep incision may be made in the part without causing any pain. This local anæsthesia is to be distinguished from the general anæsthesia, involving loss of consciousness, produced by the inhalation of chloroform, and other drugs (see p. 906). Drugs which thus diminish the sensibility of nerves have also a quieting influence on the brain, sometimes as part of their direct action, but often merely by the soothing of pain and irritation. It is a common experience that pain will, for long periods, prevent sleep, and as soon as the pain is relieved deep sleep comes on. Substances which relieve pain are called **anodynes** (Greek *a*, without, and *odunē*, pain). Such remedies not only relieve local pain, but exert a general soothing effect upon the body, lessening the activity of various organs, and quieting disordered movement. These are, therefore, called **sedatives** (Latin *sedo*, I ease or assuage), and, because of relieving spasm, **antispasmodics**. The chief of all such drugs is opium.

Opium and Morphia.—The poppy, *Papaver somniferum*, an annual herb, growing wild in Western Asia and South-eastern Europe, is the plant from which opium is obtained, for which purpose it is extensively cultivated in Asia Minor. It has a stem 3 to 5 feet high. The fruit is in the form of the well-known **poppy heads** or **poppy capsules**, which contain the seeds. In the unripe state the wall of the capsule contains branching vessels filled with a milky juice. A few days after the petals have fallen from the flower, horizontal or vertical incisions are made into the poppy capsules with a sharp instrument, not deep enough to cut through the wall of the capsule. The milky juice exudes in tears. Next day the tears, which have changed in colour from white to brown, are scraped off, transferred to a poppy leaf, and formed into cubes. There are several varieties of opium—Turkish, Egyptian, Indian, China, Persian, &c. Turkey opium is considered the finest, and is met with in round or flattened masses from ¼ to 2 lbs. in weight, covered with the poppy leaf, and surrounded with the capsules of a species of rumex (dock). It has a heavy narcotic odour, and a bitter disagreeable taste.

Opium is a very complex substance. It contains the well-known alkaloids, **morphia** and **codeia**, and no less than some seventeen others, of which thebaia, papaverine, and narcotine only need be mentioned. In good Turkey opium morphia exists to the extent of 12 to 15 per cent, and codeia only to the extent of ·2 to ·4 per cent. Morphia was discovered by Sertürner, an apothecary at Eimbeck, in North Germany, in 1816. Besides these alkaloids opium contains a substance, used separately in medicine, called **meconic acid**, and also resin, gum, odorous bodies, saline substances, &c. The preparations of opium and morphia, codeia, &c., are as follows:—

Preparations of Poppy-heads—	DOSE.
Decoction of Poppy (1 oz. bruised capsules, without seeds, boiled for 10 minutes in 15 ozs. water and strained). For external use.	
Syrup of Poppy,	10 to 60 drops.
Opium Preparations—	
Powdered Opium,	½ to 1 grain.
Laudanum (Tincture of Opium),	5 to 30 drops.
Battley's Solution of Opium (Liquor Sedativus),	5 to 20 ,,
Black Drop. (1 drop is equal to 4 drops of laudanum.)	
Nepenthe. (Same as Laudanum.)	
Scotch Paregoric (Ammoniated Tincture of Opium),	30 to 60 ,,
English Paregoric, Paregoric Elixir (Camphorated Tincture of Opium),	15 to 30 ,,
Wine of Opium (1 of opium in 10 of sherry),	10 to 40 ,,
Opium Lozenge ($\frac{1}{10}$ grain extract in each),	1 to 2 lozenges.
Extract of Opium,	¼ to ½ grain.

Opium Preparations (*Continued*):	DOSE.
Compound Opium Powder (opium, black pepper, ginger, caraway, tragacanth),	2 to 5 grains.
Confection of Opium (compound powder in syrup),	5 to 20 ,,
Pill of Lead and Opium (opium 1, acetate of lead 6, confection of roses 1),	4 to 8 ,,
Compound Soap Pill (opium 1, hard soap 4),	3 to 5 ,,
Dover's Powder (Compound Ipecacuanha Powder—opium 1, ipecacuanha 1, sulphate of potash 8),	5 to 10 ,,
Compound Kino Powder (opium 1, kino 15, cinnamon 4),	5 to 20 ,,
Aromatic Powder of Chalk with Opium (aromatic chalk powder 39, opium 1),	10 to 40 ,,
Opium and Starch Enema (see p. 874).	
Opodeldoc (tincture of opium and soap liniment, equal parts).	For external use.
Gall and Opium Ointment (p. 867).	

Morphia Preparations—

Hydrochlorate, Acetate, or Sulphate of Morphia,	$\frac{1}{8}$ to $\frac{1}{2}$ grain.
Solution of Morphia (liquor hydrochlorate of morphia, 50 drops contain $\frac{1}{2}$ grain morphia),	5 to 30 drops.
Morphia Lozenge (each contains $\frac{1}{36}$ grain morphia),	1 or 2 occasionally for cough.
Morphia and Ipecacuanha Lozenge (each contains $\frac{1}{36}$ grain morphia and $\frac{1}{12}$ grain ipecacuanha),	1 or 2.
Morphia Suppository (each contains $\frac{1}{2}$ grain morphia).	
Morphia Suppository with Soap (each contains $\frac{1}{2}$ grain morphia).	
Solution of Morphia for Hypodermic Injection (made of acetate of morphia 1 grain in 12 drops, 1 to 6 drops injected).	
Solution of Bimeconate of Morphia (same strength as laudanum),	5 to 30 drops.

Preparations of Codeia—

Codeia,	$\frac{1}{2}$ grain.
Syrup of Codeia,	1 to 2 tea-spoonfuls.

Actions and Uses of Opium.—Externally opium is used as liniment, plaster, &c., for the relief of pain, but it is doubtful whether the opium in the liniment can relieve pain acting on the unbroken skin; and it is probable that the relief is due to the warm application or to the other ingredients of the liniment. On the other hand, when the skin is broken, opium preparations are absorbed, and then relieve pain; and sometimes a blister is applied to remove the skin, and then morphia is dusted on the raw surface. When taken internally opium, morphia, &c., cause great dryness of the mouth and throat and much thirst, and quickly exert a soothing influence on the stomach and bowels. Secretion is arrested, and the movement of the bowel diminished. The result is a binding effect on the bowels, and most marked relief in inflammatory or colicky affections of the bowels. Free perspiration is caused by opium, but with this exception the activity of secreting organs is diminished. As regards its effect on the nervous system, the first effect on the brain is that of stimulation, manifesting itself in rapidity of thought, brilliance of ideas, talkativeness, exalted imagination accompanied by a feeling of exaltation, and a sense of great comfort and happiness. Or the person is inclined to lie motionless and undisturbed, while a ceaseless procession of ideas and images, of all kinds congruous and ludicrous, is passing through his mind. Following the excitement, if the dose be large enough, drowsiness comes on, and deep sleep supervenes. In very large doses it may be almost impossible to wake the person; and in poisonous doses a condition of stupor arises, the breathing becomes slow and the pulse feeble, the face is pale and with a bluish tinge, the skin clammy, the pupils of the eye are contracted to a fine point, and death occurs from stoppage of breathing.

Many people find no inconvenience from ordinary medicinal doses of opium, save that of the subsequent constipation, and dry furred tongue and much thirst. In others it produces a feeling of nausea, perhaps vomiting is induced, and great depression and headache follow after a few hours. In a few the dose of opium that would produce sleep in the ordinary individual causes restlessness and excitement and sleeplessness lasting several hours. It is quite common for even a small dose, along with considerable sweating, to produce itching of the skin all over the body, so that the person cannot rest from a desire to scratch here, there, and everywhere. Opium is one of the drugs for which tolerance is quickly established, and if it be taken regularly for any time, constantly increased doses are required to maintain the effect. The person who has developed the habit of taking opium in any of its forms suffers from intense depression and wretchedness if the usual

dose is not obtained, but becomes lively and bright after the dose. The constant use gradually exerts a most degrading influence upon the nervous system, the whole moral nature becomes perverted, and a marked tendency to meanness and lying appears. Such a habit can only be broken off by the exercise of much care and patience, by the use of doses continually being diminished by imperceptibly small amounts, and by nourishing and stimulating foods.

Women are more susceptible to the action of opium than men, and *children are peculiarly susceptible, so that opium, laudanum, or any other form should never be administered to a child by an unskilled person. One case is recorded where* 1 *drop of laudanum proved fatal to a child.*

Opium and its preparations are given for the relief of pain, specially pain about stomach or bowels; in pleurisy (p. 266) and in peritonitis (p. 190) they are the chief remedies. Given in the early stage of catarrh (p. 154), or a cold in the head, in the form of Dover's powder, opium often acts like magic; and it is sometimes a proper remedy for cough (p. 284). It is used to procure sleep, but other drugs are more suitable. In painful diarrhœa it is appropriately used. It is the chief drug used in diabetes. Its quieting effects on the circulation make it sometimes useful for internal bleeding, for which purpose it is combined with acetate of lead as the lead and opium pill. Its two principal uses are, however, to relieve pain and spasm; and whenever given for one or other of these purposes it is best given as a subcutaneous injection of morphia, which acts quickly.

Morphia has less tendency to cause sickness, vomiting, sweating, and constipation than opium itself.

Codeia, chiefly used for diabetes, is much less narcotic, and is of little use for the relief of pain.

The treatment of Opium-poisoning consists of the following measures:—Empty the stomach by a dose of 20 grains of sulphate of zinc, and if that fail to act, by means of the stomach-pump. Give draughts of strong coffee, and 4 drops of the solution of atropine (see below), preferably by subcutaneous injection, every 20 minutes (every 10 minutes if it is given by subcutaneous injection) till signs of recovery appear, or till the pupils dilate. Keep the person moving about, do everything to prevent the drowsiness overcoming him by giving him no rest, and rousing him by pulling the ears, nose, hair, &c.

Apomorphia, derived from morphia, is a powerful emetic (see p. 853), but has none of the chief properties of morphia.

Belladonna and Atropia.—Belladonna, or *Atropa Belladonna*, Deadly Nightshade, Dwale, is a herbaceous perennial plant, belonging to the same natural order as the potato—Solanaceæ—and is cultivated in England. It grows 4–6 feet high, has dark-purple bell-shaped leaves (see Plate X.), and produces purplish-black berries of the size of a cherry. The leaves are employed for making the extract and tincture, and the root is used for the liniment, and to yield the active principle, **atropia**, though it is also contained in the leaves. Its chief preparations are:—

Preparations of Belladonna—	DOSE.
Extract of Belladonna,	$\frac{1}{6}$ to 1 grain.
Tincture of Belladonna,	5 to 20 drops.
Juice of Belladonna,	3 to 10 „
Liniment of Belladonna,	For external use.
(Made from the root with spirit and camphor added.)	
Belladonna Ointment.	
Belladonna Plaster.	

Preparations of Atropia—	
Atropia,	$\frac{1}{150}$ to $\frac{1}{80}$ grain.
Liquor Atropia,	For dropping into the eye.
Solution Sulphate of Atropia	1 to 2 drops by the mouth.
Atropia Ointment.	

Actions and Uses.—When taken internally belladonna or its active principle causes great dryness of the mouth, and consequent difficulty of swallowing and thirst. This is due to paralysis of the glands of the mouth, so that no saliva is produced. In the same way the drug paralyses the sweat glands, and causes dryness of the skin, and the mammary gland, arresting the production of milk. It causes marked dilatation of the pupil, and it abolishes the power of accommodating the eyes for objects at different distances, so that the vision of near objects is blurred and indistinct. A red rash not unlike that of scarlet fever comes out on the skin with continued use of the drug. Relaxation of the bowels is produced. It flushes the face, and this flushing with the wide black pupil, gives a look of excitement to the countenance. The head feels full and the vessels throbbing. Breathing is quickened at first, and then slowed. Belladonna diminishes the sensibility of the skin, and acts also upon the muscles, in large doses causing unsteadiness of gait. The brain is stimulated by too large doses, which cause delirium, and convulsions may occur. In poisonous doses death would be due to failure of the heart and breathing.

The purposes for which belladonna or atropia is given are thus partly quite evident. It is given to arrest excessive sweating, specially the night-sweats of phthisis. A $\frac{1}{4}$ grain of the extract in pill is useful for this purpose, and it is frequently given by injection under the skin of $\frac{1}{120}$ grain atropia. The liniment used for hands, feet, or other parts, diminishes excessive sweating in these regions. A thick paint made of extract, sufficiently thinned with glycerine, is painted over the breast to arrest the production of milk. In the same way, or as plaster or liniment, it is used to relieve pain. The liquor atropia is dropped into the eye to relieve inflammation and to dilate the pupil; and belladonna is a frequent ingredient of laxative pills. The reason of all these uses is evident from what has been said.

It is a powerful drug to relieve spasm. For this purpose it is given frequently in epilepsy (see p. 123), in whooping-cough (see p. 416), in asthma (p. 273), and may be tried in St. Vitus' dance (p. 125). To relieve pain or spasm in the bowel, or genital or urinary organs, it is frequently given as a suppository, 2 grains of the extract being in each. It is one of the best remedies for bed-wetting in children; this being often not the fault of the child, but being done without its knowledge and the result of some irritation about the bladder or urinary passages. Three to 5 drops of the tincture should be given the child at bed-time. Here it may be noted that children can tolerate the drug much better than grown-up persons, and it is well in giving it to children for any purpose to begin with quite a safe dose—2 to 3 drops, and after a day or two to begin increasing the dose by a drop or two each time till 7 or 8 drops are being given. In whooping-cough this may be given three or four times a day, *the child's eyes always being watched, and an increase of the dose being stopped whenever the pupils become very wide.* Belladonna has been used as a preventive of scarlet fever, but there seems no ground for the notion that it can prevent the infection. The use of belladonna in inflammations of the eye has been referred to on pp. 371, 372. Belladonna and atropine in their action upon the skin and pupil are the reverse of opium and morphia, and they are used as antidotes in poisoning from opium or morphia (see under Opium), and also in poisoning from Calabar bean (p. 902). The latter is used as an antidote in cases of belladonna poisoning, stimulants, coffee, caffein, being also given, and the patient being kept awake if possible.

Henbane—Hyoscyamus—is a plant (*Hyoscyamus niger*) of the same order as belladonna, the leaves of which are used in medicine. It is a biennial plant, cultivated in Britain and America. It grows 2 or 3 feet high, with pale yellow 5-leaved funnel-shaped flowers (see Plate XIII.), and its fruit is a capsule, which contains the seeds, from which an active principle, **hyoscyamine**, can be prepared. Its preparations are:—

Extract of Henbane,.......	Dose, 3 to 6 grains.
Juice of Henbane, ...	,, $\frac{1}{2}$ to 1 tea-spoonful.
Tincture of Henbane or Hyoscyamus,...............	,, 15 to 60 drops.

Action and Use.—The effects of henbane resemble very much those of belladonna and stramonium. It allays spasm, and is used mainly for that purpose, being added to purgative pills to make their action easy. It is also often used to allay irritability of the bladder. It is given in nervous diseases to diminish excitement and spasm, but in large doses causes delirium like belladonna. It is useful also in affections of the lungs and air-passages, attended by much irritable cough, or in spasmodic diseases connected with these organs.

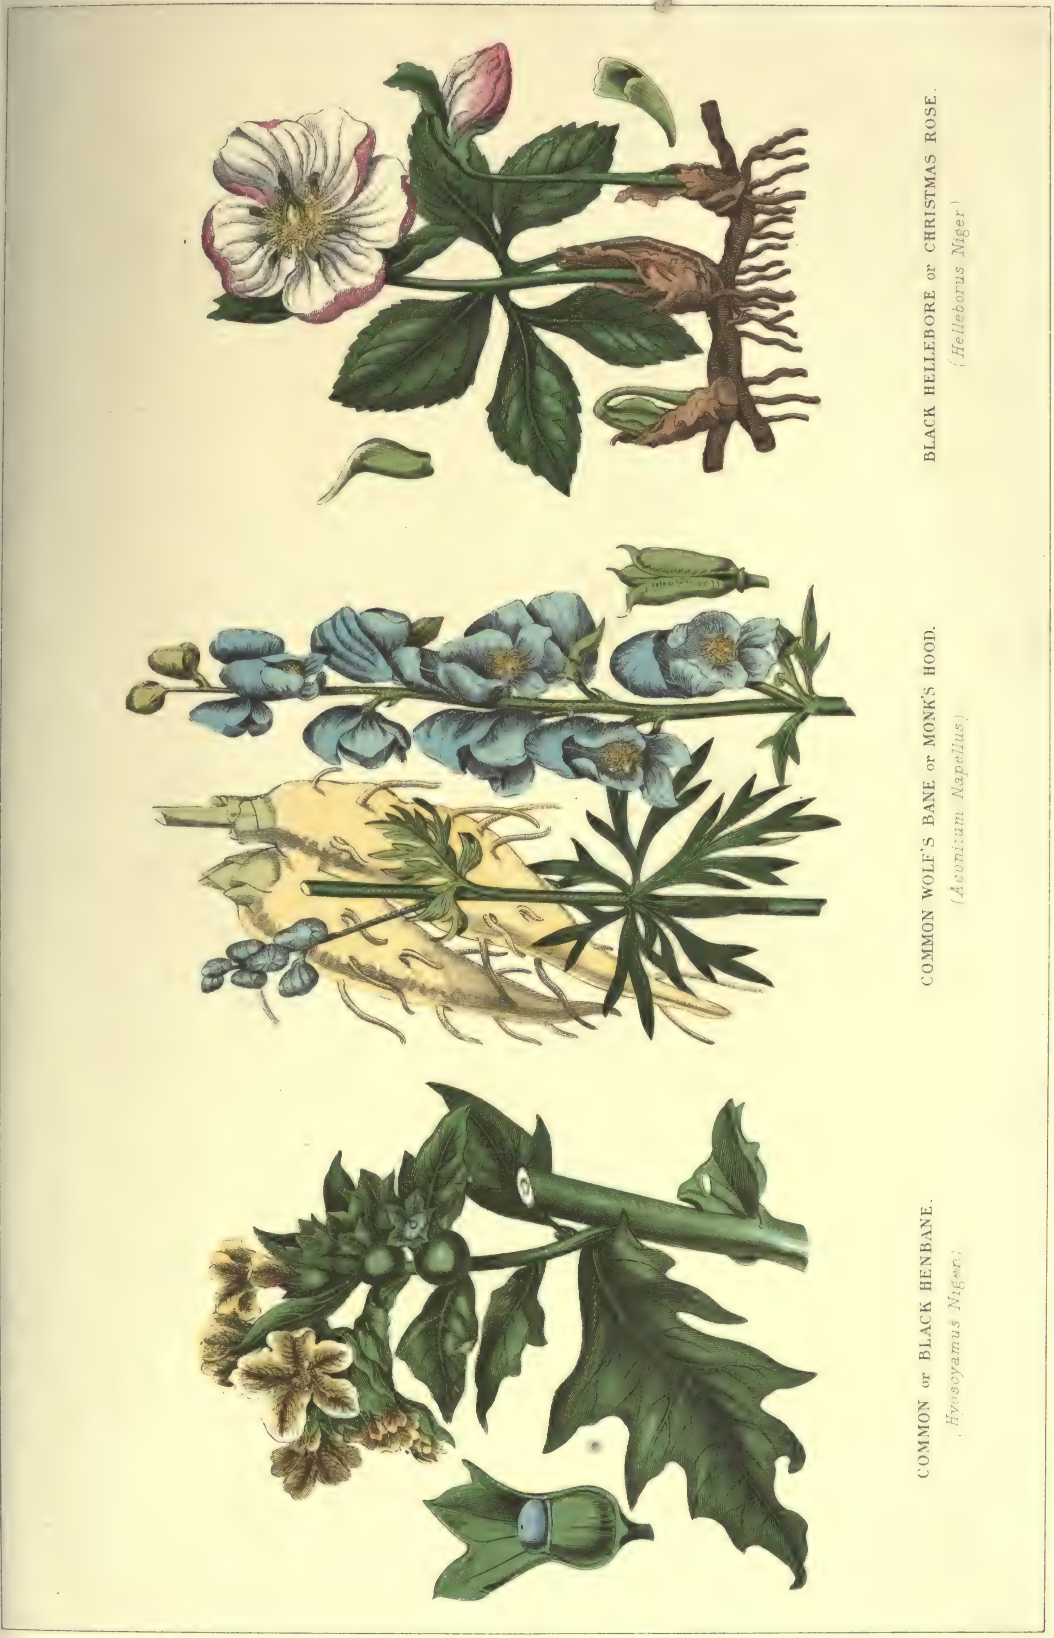
Poisoning by henbane should be met by emetics, warmth to the extremities, cold to the head, and stimulants, particularly coffee.

Stramonium, the leaves and seeds of *Datura Stramonium,* of the Solanaceæ order. It is also called Thorn-apple, and in the United States of America, Jamestown or Jimson weed. It grows as a weed in waste places. It is an annual about 2 feet high. Its leaves, dark green on the upper surface, are pale green below; the flowers are large, white, funnel-shaped, with five points (Plate XII.); the fruit is a capsule beset with spines and contains numerous kidney-shaped seeds. The fresh plant has a heavy narcotic disagreeable odour. A variety which resembles it very closely is *Datura tatula,* but its flowers are purple in colour. All parts of the plant yield a principle which, if not identical with atropine, is a mixture of atropine and hyoscyamine (called **daturine**). The leaves are used in the dry state for smoking; of the seeds the following preparations are made:—

Powdered Leaves,................	Dose, 1 grain.
Extract of Stramonium,........	,, $\frac{1}{4}$ to $\frac{1}{2}$ grain.
Tincture of Stramonium,.......	,, 10 to 20 drops.

Stramonium, belladonna, and henbane cannot be distinguished in their effects from one another when given in corresponding doses, as is to be expected, since their active principles are

Plate XIII.



COMMON or BLACK HENBANE.
(Hyoscyamus Niger.)

COMMON WOLF'S BANE or MONK'S HOOD.
(Aconitum Napellus.)

BLACK HELLEBORE or CHRISTMAS ROSE.
(Helleborus Niger.)

practically identical. Stramonium, like belladonna, produces dryness of the throat, dilatation of the pupils of the eye, delirium, and, in poisonous doses, convulsions and death. It is specially employed to relieve spasm of the respiratory organs, and its main use is for asthma, for which the leaves are smoked like tobacco (p. 273). About 15 grains of dried leaves may be smoked at once, or half that quantity of the fibres of the dried root mixed with sage-leaves or tobacco, in a pipe or cigarette; or tobacco steeped in a strong decoction of stramonium may be used, or cigars similarly treated. Opium is the antidote to poisoning by this drug, and especially morphia given by injection under the skin. In one case 15 grains of hydrochlorate of morphia were required, *given by the mouth*, before the patient was out of danger.

Tobacco.—The tobacco plant (*Nicotiana tabacum*) belongs to the same order as belladonna, henbane, and stramonium. It is indigenous to tropical America. It is an annual plant 4 to 6 feet in height, with a stout heavy stem, with numerous dull-green leaves, those near the root being often 2 feet long and 4 or 5 inches broad. The flowers are rose-coloured, funnel-shaped, with united petals 5-pointed. The fruit is a capsule containing numerous small kidney-shaped seeds. The plant was brought, it is believed, from Virginia. The generic name "Nicotiana," was bestowed on it in honour of Jean Nicot, ambassador of Francis II. in Portugal, "who brought some tobacco from Lisbon and presented it to Catherine de Medicis, as an herb possessing valuable properties; hence also it has been termed **queen's herb**. By some persons the name tobacco is said to have been given to the plant by the Spaniards, who took it from Tobaco, a province of Yucatan, where they first found it and learned its use; others derive it from the island of Tobago; but Humboldt asserts that the word tobacco (tabacco), like the word savannah, maize, cacique, maguey (agave), and manatee, belongs to the ancient language of Hayti, or Saint Domingo; and that it does not properly denote the herb, but the tube through which the smoke is inhaled." The same authority asserts that Europe received the first tobacco-seeds from Yucatan in 1559, and that its cultivation in Europe preceded that of the potato by 120 or 140 years. When Raleigh brought it to England in 1586, it was already largely cultivated in Portugal.

When tobacco is burned it yields about 14 to 18·5 per cent of ash, consisting of salts of potash, lime, and ammonia. It contains besides albumin, gum, resin, extractives, and a powerful principle **nicotine**, and a volatile oil **nicotianin**. Nicotine is a colourless, oily-looking fluid, with an irritating tobacco-like odour and an acrid taste, and was discovered by Posselt and Reimann in 1828. Of this active principle dried tobacco-leaves contain from 2 to 8 and occasionally as high as 11 per cent. This is present in all parts of the plant and is present also in tobacco-smoke. But it would appear that by the burning process much, if not all, of the nicotine disappears and other compounds are formed, whose character varies according as the air has a more or less free access to the burning tobacco. When burned in a pipe a substance called **pyridine** is chiefly formed, but when burned in cigars another substance is formed called **collidine**, which is far less active than pyridine. In the United States an oil of tobacco is prepared by dry distillation of coarsely-powdered tobacco, a wine of tobacco by exhausting 120 grains of tobacco with 4 ounces of sherry, and an ointment made of an aqueous extract of ½ oz. of tobacco and 8 oz. lard; an enema of tobacco is made with 20 grains of tobacco infused in 8 oz. boiling water for half an hour. It used to be employed to produce depression and relaxation in strangulated hernia, and in dislocation, the great muscular depression permitting easy reduction of the dislocation, and also for obstinate constipation and retention of urine; but chloroform has taken its place in the former circumstances, and other substances in the latter. Tobacco acts as an irritant to stomach and bowels, producing copious flow of saliva, sickness, vomiting, colic, and purging. Smoking may produce like effects, the use of snuff, or the application of the leaf to the skin. That is why tobacco is found to relax the bowels, while at the same time, by producing a catarrhal condition, it may give rise to indigestion. The effect of nicotine on the heart is to slow it at first; the beat is then quickened and finally becomes slow and weak, while the face is pale, and a tendency to faint arises. Small doses first slightly excite the nervous system; larger ones cause depression, ending in great muscular tremulousness, convulsions and paralysis; and death is caused by paralysis of the respiratory muscles.

Tobacco used to be employed for itch, but the risk of poisoning was considerable; the smoke was used for asthma and the enema to produce muscular weakness. It is not now employed for such purposes. As to the effects of tobacco-smoking, they are both mildly stimulating and

soothing to the nervous system, and in moderation tobacco-smoking cannot be said to be injurious to many people, though some are so susceptible to its influence that the smallest amount is positively injurious. On the other hand excessive tobacco-smoking is undoubtedly on the increase, and its evil effects are perfectly recognizable and well marked. Apart from furred tongue, dryness and irritability of the throat, there is a bad effect on the stomach and heart. Irritable dyspepsia arises, indigestion with severe heart-burn is common, and palpitation of the heart of a particular kind (smoker's heart). This disappears if smoking is given up for a time. One of the effects of excess in tobacco which is most familiar to the author is dimness of vision, due to an effect upon the nervous structures of the eye, which is called **tobacco amblyopia** or tobacco blindness. In the author's experience it is very common when a smoker consumes between 3 and 4 ounces of tobacco per week. Of course many escape, it is indeed only the comparatively few that go to excess who suffer from loss of sight, yet one never can tell what smoker to excess will escape and who will be caught. The author has not found such tobacco blindness arising if the smoker restricted his supply to 2 oz. per week, though the digestive and heart symptoms may arise from even less. The only remedy for such a state of things is remorselessly and resolutely to cut off the tobacco.

An emetic, followed by stimulants, is the appropriate treatment for poisoning by tobacco.

Indian Hemp, the flowering tops of the female plant of *Cannabis sativa*, grown in the East Indies, which are pressed together in masses and held so by the resin adhering to the fresh tops. One form of it used in India is called by the Arabs **hashish**, by the Indians **bhang** or **siddhi**; the form sent to market is called **gunjah** or **ganga** and **guaza**; while to the resin itself, which may be scraped off the tops, the name **charas** or **churrus** is given. Indian hemp contains a resin called **cannabin** and a volatile oil, **cannaben**.

Its preparations are:—

Extract of Indian Hemp, ...	Dose, $\frac{1}{4}$ to 1 grain.
Tincture of Indian Hemp,.....	,, 5 to 10 drops.

Indian hemp produces a species of intoxication, in which the person's ideas of the natural relations of things become perverted. The patient may, in his disordered imagination, pass through the experience of days and weeks all in a few minutes; his own personality may become of enormously increased importance; faint whispers seem to his ear tones of thunder; and all sorts of fantastic pictures appear to his mind. With different individuals, however, various effects may arise. Some may be made only drowsy and depressed. Sleep and stupor follow the intoxication, pain and spasm being diminished. Coffee and tobacco increase the effects of the drug. In an instance, occurring in the author's experience, the person, who had taken of his own accord $\frac{1}{4}$ grain of extract in pill for headache, felt no particular effects till $1\frac{1}{2}$ hours after, when, having taken dinner, he sat down to enjoy a cigar. The tobacco quickened the influence of the drug, and when seen the person was walking up and down his room without cessation, evidently suffering from acute depression. He complained of a great feeling of anxiety, and intense restlessness which would not permit him to stop his walk for an instant. At the same time his limbs felt like lead, but he walked without difficulty or unsteadiness. Every now and again a wave of depression would pass over him, during which, though spoken to, he would not utter a word. Shortly that would pass off, and then he would talk freely describing his sensations, until another wave of depression would suddenly cause his tongue to cease though his feet kept their restless pacing to and fro. Of course, at no time was he in danger. Someone had advised him to take an emetic of mustard and water, and of that he took two tumblersful, but without effect, the drug having so quieted the stomach. Hot stimulants would have been a more appropriate remedy. Indian hemp is used to relieve pain and to procure sleep, when opium is likely to disagree. It is in cases of painful monthly illness, and in recurring sick headache, that it has been specially used. It has been lauded in the treatment of tetanus—lock-jaw. In India it is often used by being smoked in a pipe.

Calabar Bean, ordeal bean, the seed of the *Physostigma venenosum*, a woody climber somewhat resembling the Spanish bean or scarlet runner, growing near the mouths of the Niger and Old Calabar river in Western Africa. It contains an active principle, called **physostigmin**, or more commonly **eserin**. Its preparations are as follows:—

Powdered Calabar Bean,......	Dose, 1 grain.
Extract of Calabar Bean,.....	,, $\frac{1}{16}$ to $\frac{1}{4}$ grain.
Tincture of Calabar Bean,....	,, 10 drops.
Eserin,............................	,, $\frac{1}{60}$ to $\frac{1}{20}$ grain.

Calabar bean acts chiefly upon the spinal cord, the excitability of which it greatly reduces and in large doses abolishes. The result is a

loss of power over voluntary movements, and diminished sensibility of the skin. Besides these symptoms there are intense prostration, pallor, weak pulse, shortness of breath, and marked contraction of the pupil of the eye. Consciousness is not impaired; sickness, vomiting, diarrhœa, and much perspiration may occur. Poisonous doses cause death by paralysis of breathing. One of the chief uses of the drug is in tetanus (lock-jaw, p. 126), for which it has been shown to be one of the most useful drugs. It is recommended to be given in doses of $\frac{1}{3}$ grain of extract every quarter of an hour till the spasms cease; the action of the drug should be maintained till the tendency to recurrence of the spasm ceases. Another chief use of the drug is in the form of a solution of eserin, dropped into the eye to contract the pupil. For this purpose it is used in glaucoma (see p. 375), though an operation is the chief treatment of this affection. The drug also is antagonistic to belladonna, in poisoning by which it could be used; and, of course, belladonna, or its active principle atropia, would be an appropriate remedy in poisoning from Calabar bean, coffee and other stimulants being also given.

Hemlock, the Poison or Spotted Hemlock, or *Conium maculatum* (Plate XI.), a plant of the natural order Umbelliferæ, which grows wild in Britain. The leaves are gathered when the fruit begins to form, and the full-grown fruit is also gathered and dried for use in medicine. Both leaves and fruit contain an active principle, **conia.** Its preparations are:—

Powdered Hemlock Leaf,	Dose, 2 to 8 grains.
Green Extract of Hemlock,	,, 2 to 6 ,,
Alcoholic Extract of Hemlock,	,, 2 grains.
Fluid Extract of Hemlock (American),	,, 15 drops.
Compound Pill of Hemlock,	,, 5 to 10 grains.
Juice of Hemlock (expressed from the fresh leaves with added spirit),	,, 30 drops to 2 tea-spoonfuls.
Tincture of Hemlock (made *from the fruit*),	,, 20 drops to 1 tea-spoonful.
Vapour of Hemlock (see p. 885).	

The chief action of hemlock is upon the nerve-endings in the voluntary muscles, which they paralyse, so that weakness of the legs and a staggering gait, ending in complete loss of power, are the chief symptoms of large doses. Sensation is not affected, nor the mental functions. The eyelids fall, the pupils dilate, the hands and feet are cold, speech is slow and difficult, and the voice hoarse by relaxation of muscles; and in fatal doses death is caused by paralysis of breathing, and is sometimes accompanied by convulsions. Its chief use is for the relief of cough as vapour, and for St. Vitus' dance.

The treatment of poisoning by conium is an emetic, hot stimulants, and the external application of heat.

The Lesser Hemlock, Fool's Parsley (*Æthusa cynapium*, Plate XI.), was supposed to be a poisonous plant, but recent investigations have shown it not to be in any degree poisonous, the error having arisen from its strong resemblance to conium.

Curare, Woorare, Urari, the South American arrow-poison, is a mixture of various substances, the chief of which is a variety of Strychnos. Its chief effect is to paralyse the nerve-endings in muscle, in large doses the sensory nerves also, and later the spinal marrow. Great relaxation of the muscle is, therefore, produced, the eyelids sharing in the paralysis so that the eyes cannot be opened, and there is complete loss of power over the body, death occurring by paralysis of breathing. The poison is rapidly removed from the body by the kidneys, and if breathing be artifically maintained recovery is likely to occur. The drug has been used chiefly in the treatment of spasmodic diseases, such as lock-jaw, hydrophobia, epilepsy, St. Vitus' dance. In hydrophobia and tetanus it has been given by injection under the skin, $\frac{1}{10}$ grain in watery solution.

Yellow Jasmine, the dried root-stock and rootlets of *Gelsemium sempervirens*, from which the following preparations are made:—

Alcoholic Extract of Gelsemium,	Dose, $\frac{1}{2}$ to 2 grains.
Fluid Extract of Gelsemium (American),	,, 5 to 20 drops.
Tincture of Gelsemium (British Formula),	,, 5 to 20 ,,
Tincture of Gelsemium (American Formula),	,, $\frac{1}{2}$ to 2 tea-spoonfuls.

This is a drug which produces blunting of general sensibility, and in large doses languor, dizziness, impaired sight, drooping eyelids, muscular relaxation, feeble irregular pulse, and death through arrest of breathing. It has been much used in America and for many diseases. That in which undoubted benefit has been obtained from it is neuralgia of the face, specially that

due to cold or rheumatism. It is a drug about which much care needs to be exercised, small doses often producing alarming symptoms. Numerous cases of death from its use have been recorded in America. Morphia, injected under the skin, is said to be the proper remedy, after the stomach has been emptied by an emetic. Stimulants, ammonia, coffee, and whisky should be freely administered, and heat applied to the body.

Cocaine, the acting principle of *Cuca* or *Coca*, described at p. 663. Its preparations are as follows:—

	DOSE.
Coca Wine,	a wine-glassful.
Liquid Extract of Coca,	1 to 4 tea-spoonfuls.
Fluid Extract of Coca (American),	½ to 2 ,,
Extract of the Green Coca Leaves,	5 to 15 grains.
Cocaine,	⅙ to ½ grain.

The effects of coca have been described on p. 663. The wine and liquid extracts are used for their tonic and stimulating effects, in fatigue, and to produce sleep. The active principle, cocaine, when applied to the skin or mucous membrane, destroys sensibility for a time. Applied to the tongue or mouth and throat it completely blunts the sensibility, so that taste cannot be felt. A drop or two of a 4 per cent solution let fall into the eye abolishes sensation, so that simple operations can be performed without pain. Injected into the gum round a tooth it will so lower the sensibility that the tooth can be extracted without pain. It is for such purposes it is chiefly employed. It can produce poisonous effects in too large doses. Large doses cause a feeling of fulness in the head, great restlessness, giddiness, headache, and even delirium; and death results from stoppage of breathing. Stimulants are the appropriate remedy.

Among other remedies for nerve pain are **Antipyrin,** noted on p. 821, and **Phenacetin.** The latter drug is like the former used to reduce temperature in fevers, being given in doses of 8 grains. Both relieve pain, and are valuable in nervous headache and neuralgia.

Drugs which Procure Sleep.

Drugs which procure sleep are called **hypnotics** (Greek *hupnos*, sleep), or soporifics (Latin *sopor*, sleep, and *facio*, I make), terms applied to remedies which calm and soothe the nervous system so that sleep naturally ensues, without being absolutely compelled, as it were. The drugs which act much more strongly and compel sleep, which is then of the nature of a stupor, are called **narcotics,** from Greek *narke*, deep sleep. One and the same drug may be used in both ways, that is to say, a small dose of the drug may be sufficient to procure sleep simply by so relieving pain or restlessness that sleep is not prevented; while it may also be given in a large dose to produce a narcotic effect. Such a drug is opium with its preparations. When a person is under its full influence, vigorous and, in ordinary circumstances, painful impressions may be made upon his body without producing the slightest response. It has been already sufficiently described on p. 897.

Chloral Hydrate is formed by passing chlorine gas through absolute alcohol. It was discovered by Liebig in 1832. It is in the form of colourless crystals of a peculiarly pungent smell and taste.

	DOSE.
Chloral Hydrate,	5 to 20 grains.
Syrup of Chloral Hydrate,	½ to 2 tea-spoonfuls.
(10 grains in each tea-spoonful.)	

Actions and Use.—Chloral hydrate is an irritant to the skin, has a hot burning taste, and applied to a raw surface acts as a powerful irritant. A solution of 5 grains to an ounce of water acts as an antiseptic, preventing decomposition. When it is given internally in doses of 20 grains or thereby it quickly induces sleep, of a natural and refreshing character, the awaking from which is unattended by the headache, sickness, confusion, or feeling of stupidity that usually follows sleep procured by opium. In larger doses the sleep is deeper and more prolonged; the person can with difficulty be awakened from it; pain is abolished; breathing becomes slow and shallow; and the pulse, quickened at first, is afterwards slowed; the pupils are much contracted; and there is complete muscular relaxation. This last effect, with the abolition of pain, is due to the action of the drug upon the spinal marrow. The result of poisonous doses is a great fall in bodily heat and paralysis of the heart. In animals death by chloral poisoning has been prevented by means which maintain the bodily heat, and the treatment of **chloral poisoning** consists in the use of warm blankets, hot bottles, hot stimulants such as hot coffee, hot toddy, &c. The taste for chloral hydrate is apt to grow upon one so that its use cannot readily be given up. When taken habitually, it is apt to produce irritability of the stomach, nervous irritability also, and skin eruptions. With constant use larger doses require to be taken; and persons who are accustomed

to its use are very apt some day, owing to their familiarity with the drug, to take an overdose, a very slight increase of an accustomed dose being sometimes sufficient to cause death. Chloral hydrate is chiefly used to procure sleep, when it is difficult to obtain owing to nervous excitement, as the result of overstrain or worry, in feverish diseases, and in conditions of delirium and insanity, and specially in delirium tremens. It is not nearly so useful for the relief of pain. No drug can compare with opium for such a purpose; and it is useless to use it for neuralgia. It is useful in convulsions, and may be used in cases of convulsions in children, to whom in proper doses it may be given with comparative safety, while opium is for them a most dangerous drug. The dose of chloral for children is 1 grain for each year of the child's age. It is beneficial in sea-sickness. It is the antidote to poisoning by strychnine.

Chloral with Camphor, or Camphorated Chloral, is a mixture of equal parts of chloral hydrate and camphor rubbed together in a mortar. It is a colourless liquid of syrupy consistence. It is used for painting over painful parts in neuralgia and rheumatism.

Croton Chloral Hydrate, or Butyl Chloral Hydrate, is a drug which acts similarly to chloral hydrate. It is made by passing chlorine gas through, not alcohol, but acetic aldehyd. Its dose is from 2 to 15 grains. It is said to act less quickly and surely than chloral hydrate, but to depress the heart less. In particular it lowers the sensibility of nerves of the skin, specially of the sensory nerve of the face. On this account it has been recommended for neuralgia of the face, and tic douloureux along with gelsemium (p. 903); and it has proved useful in cases of nervous headache and painful monthly illness.

Bromal Hydrate is a drug prepared like chloral hydrate, the vapour of bromine being substituted for chlorine. It is very irritating, and cannot be taken internally unless largely diluted, because of burning in the throat, and vomiting and diarrhœa arising owing to irritation of gullet, stomach, and bowels. It is poisonous in smaller doses than chloral, and there is no good reason why it should be used at all.

Bromides of Potassium, Sodium, and Ammonium.—These are salts of bromine with potash, sodium, and ammonium. Bromine is one of the elements, a brownish-red liquid, readily converted into vapour, orange-red in colour, and intensely irritating to throat and eyes. It is obtained from sea-water. The bromides of potash, soda, and ammonia are all used for their soothing effects upon the nervous system. They diminish the excitability of all sensory nerves, acting also upon the spinal cord and brain. The activity of the brain they greatly lessen, and are specially valuable on this account in getting rid of sleeplessness due to restlessness and excitement. In such cases a dose of 10 to 15 grains, taken a short time before going to bed, may be enough to quiet down the brain sufficiently to cause natural sleep. They are particularly useful in delirium tremens, and may for this be combined with chloral hydrate. The bromide of potassium is the most common drug for convulsive diseases, such as epilepsy and child-crowing. It relieves sickness in pregnancy; and the delusions that occasionally trouble pregnant women in the later months are commonly removed by it. With prolonged use of the bromides a condition called **bromism** arises, one of whose symptoms is an eruption of pustules, specially on the face, as well as unsteady gait, impaired memory, and other symptoms of dulled mental power. Bromide of sodium has the same uses as the bromide of potassium, but is less depressing; of the bromide of ammonium the same may be said. It is commonly used with belladonna for whooping-cough. The great advantage of the bromides is safety in their administration. They are most valuable in children's diseases, for which they need never be given in less than 5-grain doses. In convulsions they are the invariable remedy, and they may be given at times when children are apt to be peculiarly restless and irritable, such as the period of teething. At the same time, while they are thus safe, they are never to be given indiscriminately and for the mere sake of saving mother or nurse some little trouble by inducing sleep in the child.

Monobromated Camphor is a compound of camphor and bromine, which produces sleep like the bromides. It has been recommended for that purpose in nervous sleeplessness, in St. Vitus' dance, and in hysteria, and it has been used in epilepsy. Its dose is 2 to 10 grains, and it is given in pill.

Paraldehyd.—Aldehyd is formed by the oxidation of alcohol, a stage before the production of acetic acid, into which pure aldehyd readily passes. Paraldehyd is obtained from aldehyd by treatment with dilute sulphuric or nitric acid. It is at ordinary temperatures a colourless liquid, but becomes crystallized if cooled below 50° Fahrenheit. It has a peculiar ethereal odour. Given in doses varying from 15 to

60 drops, it produces sleep for several hours, leaving behind no headache, digestive disturbance, or other unpleasant symptom. It does not depress the heart. It increases the flow of urine, but has no effect on the skin. It is in sleeplessness, both that due to nervous conditions, and that due to acute disease, and in mania and delirium, particularly delirium from drink, that it is most serviceable. It may be given in 30-drop doses, repeated thrice, at intervals of half an hour, if required. If it fails then to act it need not be continued.

Urethane, or Ethyl Carbamate, is another recent remedy for sleeplessness, which, while producing the tranquil effects of chloral hydrate, has none of its depressing effects upon the heart and respiration. It quiets the brain excited by worry or overwork, and puts it in a condition for natural sleep. Its dose is 4 to 8 grains, repeated every half hour, for 4 or 5 times, till sleep is obtained, or 15 to 30 grains given in one dose; but it is best given in small doses frequently repeated, as vomiting is apt to occur after a large dose. It is said to be an antidote to strychnia poisoning.

Sulphonal is the most recent of all drugs for the production of sleep. It was prepared by Professor E. Baumann, of the University of Freiburg, and described by him in 1888. In doses of from 16 to 60 grains, it produces in from ½ to 2 hours a quiet natural sleep, from which the patient awakens refreshed in from 5 to 8 hours, without any feeling that would suggest that the sleep had been anything but natural. It is free from the disagreeable effects of opium, and the heart-weakening produced by chloral. In simple sleeplessness, in the sleeplessness of fevers, in sleeplessness in lunatics, &c., it may be given with good results and without fear. The author has, from his own experience, formed a high opinion of its value. He finds 15 grains, given at bed-time, to be generally successful in obtaining an uninterrupted sleep for fully 8 hours, with no subsequent bad effects. In his opinion it is far superior to urethane and paraldehyd, from which he failed to get any very satisfactory results in the limited number of cases in which he employed them, while sulphonal yielded immediate benefit.

Chloralamid is another of the newer remedies. It is obtained from chloral hydrate. It occurs in colourless crystals with a faintly bitter taste. Its use is advocated in sleeplessness, in the course of nervous and heart affections, and enteric fever. It is given in 20-grain

doses in a little spirit and water, or in a slightly acid solution.

Chlorobrom is a mixture of chloralamid and bromide of potassium, of each 30 grains in one ounce of water. The dose is one table-spoonful in water. It is recommended in sleeplessness, specially of nervous origin. It is highly praised as a preventive of sea-sickness. A table-spoonful should be taken on going on board ship, and the person should at once go to his berth and lie down. In an hour a second similar dose may be taken, and in another hour a third dose if necessary.

Drugs which Destroy Consciousness: Anæsthetics.

We have already noted in this section several drugs which, locally applied, relieve pain by lessening sensibility, such as cocaine, which are, therefore, rightly enough called **local anæsthetics.** But in the following paragraphs we must consider a number of drugs which produce a diminution of sensibility all over the body, and not merely at one part. Then we have seen that opium, chloral hydrate, Indian hemp, &c., diminish sensibility and relieve pain, and are capable of producing an anæsthetic influence, and abolishing consciousness. They do this, however, as their final effect, the loss of consciousness coming as the crowning effect of a large dose, and such doses as are attended by dangerous weakening of the heart and breathing before the loss of consciousness is obtained. The drugs we are about to consider, on the other hand, suspend consciousness almost to begin with, only later and with continued administration acting injuriously upon the nerve-regulating apparatus of heart and breathing. Where, then, it is a question first and foremost of abolishing consciousness for the removal of pain, or preparatory to the performance of a painful operation, these manifestly are the drugs to be employed. The chief of them are chloroform and ether.

Chloroform is obtained from alcohol by the action of chlorinated lime, the production of chloral being one of the stages in the process. It is a compound of carbon, hydrogen, and chlorine, one combining weight of each of the former to three combining weights of the latter; and it is represented by the formula $CHCl_3$. It is a limpid colourless liquid, of an agreeable ethereal smell, and with a sweet hot taste. It mixes readily with spirit, olive-oil, and turpentine, but requires much water for solution. Its dose and preparations are as follows:—

	DOSE.
Chloroform,	3 to 10 drops.
Chloroform Water (1 of chloroform, 200 of water),	½ to 2 fluid ounces.
Spirit of Chloroform—Chloric Ether,	10 to 60 drops.
Compound Tincture of Chloroform, (Chloroform 2, spirit 8, compound tincture of cardamoms 10.)	10 to 60 ,,
Chloroform Mixture (American), (Chloroform 8, camphor 2, fresh yolk of egg 10, water 80.)	1 to 2 table-spoonfuls.
Liniment of Chloroform (equal parts of chloroform and liniment of camphor).	For external use.

Actions and Uses.—Chloroform has two different effects when applied to the skin, according as the skin is covered over when the chloroform has been put on or left uncovered. In the latter case it quickly evaporates, cools the skin, diminishes sensibility, and reduces pain; in the former case it acts as an irritant, reddens the skin, producing heat and pain and even blistering, but ends by diminishing the sensibility of the part. It is, therefore, used in various circumstances as a liniment for neuralgia, lumbago, and for application to a painful tooth, &c. When taken by the mouth it produces a hot burning sensation in the mouth, gullet, and stomach; and, when it reaches the stomach, acts in the first instance as a stimulant, expelling wind and relieving griping. For this purpose the compound tincture or the mixture of the American Pharmacopeia is the most useful preparation. In large doses it will irritate the stomach and bowels, causing at first pain, vomiting, and purging, but, when absorbed into the blood, it will, by diminishing sensibility, cause the pain to cease; and if the dose has been large enough will cause unconsciousness. Apart from its use as a liniment and for flatulence, it is given directly for its effects upon consciousness; and for that purpose is given as vapour. The person to whom it is to be administered lies upon a bed or couch, all tight articles of clothing, especially about the neck and waist, being removed; the chloroform is dropped upon a folded towel, which is held above the mouth and nostrils, *not touching them*, a space being between the face and the towel, so that air readily passes in to be inhaled. It is not thus pure vapour of chloroform that is inhaled. Very far from that is desired. Indeed, the vapour of the chloroform is, when undiluted, irritating to the air-passages just at first, and could not be respired. When a patient is being put under chloroform, if the towel be held too close to the mouth so that the vapour is too strong, arrest of breathing and spasmodic cough are produced from the irritating effects. The air, therefore, requires to be charged with only a small percentage of chloroform vapour, and this being inhaled gradually blunts the sensibility of the respiratory passages, so that soon a stronger charge can be inhaled, and the towel can be gradually approached. Indeed, throughout the whole procedure of the administration of chloroform, success and freedom from danger depend upon the proportion which the pure atmospheric air and the vapour of chloroform inhaled hold to one another, excess of the chloroform vapour tending to the production of symptoms of poisoning by arrest of breathing or stoppage of the heart, while if the chloroform is properly administered unconsciousness can be maintained for prolonged periods without danger. When chloroform is inhaled thus the first effects are stimulating to the brain. It is the brain that is at the very outset affected. Noises are heard in the ears, feeling and imagination are exalted. Thereafter excitement becomes pronounced, and the patient begins to talk loudly and rapidly or to sing, while gesticulation and often violent struggling ensues, till the chloroform begins to act more powerfully, when the muscles become weakened, the movements are irregular, feeble, and easily controlled, and complete relaxation results. At this period there is complete unconsciousness. Some amount of voluntary power may remain, so that the reflex starting of a limb might occur, if a painful impression were made upon it. But with a little longer inhalation this too ceases, and now any operation can be undertaken without the slightest impression being produced on the patient. The nerve centres which control the breathing and the action of the heart are in full activity. In the previous stage both are highly stimulated, so that the pulse is quick, very quick, and the breathing is also more rapid. But as the chloroform acts the speed diminishes, till, when the appropriate time for operation is reached, the pulse should be strong, full, steady, and at a usual rate of rapidity, and the breathing is regular and deep. Indeed, one accustomed to administer chloroform can gauge by the pulse the proper amount to administer. If the administration be continued beyond the stage now

reached, paralysis of the heart and breathing would arise, the heart beating feebly and irregularly, or suddenly ceasing altogether, and breathing becoming irregular and feeble or arrested. Therefore, as soon as the proper stage has been reached, the inhalation is suspended by removal of the cloth from the neighbourhood of the face, and the patient breathes pure air. As soon as a return to consciousness is indicated by some slight movement, the inhalation is resumed, and so on. Chloroform thus acts upon the highest nerve centres first, abolishing control, then arresting all the mental functions, subsequently destroying sensibility and power of motion, and only, last of all, paralysing the nerve functions which preside over the circulation and breathing. Many people take chloroform with perfect quietness, and without making the least sound or struggle from beginning to end of its administration.

Death by chloroform is most commonly due to stoppage of breathing. It is to be met by all measures which stimulate the breathing—slapping the chest with towels wet with cold water, artificial respiration, &c., care being taken that abundance of pure air is being driven on to the patient from open windows, &c. Breathing may stop because of mechanical obstruction by the falling back of the tongue. This is met by pulling the chin forwards by the fingers hooked under it, and by catching the tongue and pulling it forwards. If the heart stop suddenly, indicated by pallor of lips and face, the patient's head should be quickly lowered, friction and hot sponges used over the heart, and artificial respiration carried on. Sickness is frequent during the administration of chloroform, and is best avoided by the patient having no solid food for several hours before administration; a cup of beef-tea two or three hours before is valuable. After the administration the patient should be kept lying flat and quiet for two hours before any food is given, which may then be cold beef-tea, jellies, &c. After twelve hours, ordinary food, if otherwise suitable, is returned to.

Chloroform must never be given by any unskilled person; and it would be the height of folly for a patient to attempt to administer it to himself.

Chloroform is given not only for the production of unconsciousness to permit of surgical operations, but also for the relief of pain such as accompanies the passage of a calculus or gall stone, for the arrest of convulsions in either adults or children, and in child-bearing. In the latter case it is not necessary to push the administration so far as for surgical operation, unless the employment of instrumental means of delivery is required.

n

It is generally supposed that any affection of the heart would be an indication against the administration of chloroform. This is not so. It suggests, of course, the necessity of great care in its administration. But if any heart affection exists, the incomplete administration of chloroform during an operation would be attended by more risk than its complete administration. The necessity exists, in such cases, of guarding the heart from shock, and this is best done by producing complete anæsthesia. Many of the deaths during chloroform inhalation have apparently occurred because enough had not been given, and the impression made by the operation upon sensory nerves had by reflex action caused sudden arrest of the heart.

Ether.—Sulphuric ether is prepared from alcohol by distillation with sulphuric acid. It is a compound of carbon, hydrogen, and oxygen, and has the formula $C_4H_{10}O$. It is a colourless, very volatile liquid; and highly inflammable.

	DOSE.
Ether,	20 to 60 drops.
Spirit of Ether (Hoffmann's Anodyne),	30 to 60 ,,

Ether evaporates with great rapidity, and it is, on that account, applied to the skin as a spray either to relieve pain by its cooling effect, or by freezing the part to permit of incisions being made without causing pain. As with chloroform, if it be applied under cover it reddens and blisters the skin. It is used, like chloroform, specially in the form of spirit of ether, as a stimulant to the stomach to expel wind and relieve spasm. At the same time it stimulates the heart, and is employed in palpitation, faintness, and depression because of its rapid action. In hysterical flatulence it is very useful, and in spasmodic cough and asthma. Ether is employed in exactly the same way as chloroform to abolish consciousness and permit surgical operations. It has advantages over chloroform for this purpose, but disadvantages also attend its use. It has been shown to have a much less paralysing influence on the heart than chloroform, and death from heart failure is a much less likely occurrence under the administration of ether than chloroform. It is, therefore, a safer anæsthetic. But the stimulating effects of ether are more prolonged than those of chloroform. It takes a much longer time to induce complete insensibility; there is much more struggling and violence; and more irritation of the air-passages with the vapour,

so that even a catarrh may be brought on by its use. The inflammability of ether renders it necessary to be on guard against a light being brought near when it is in use. The risks of chloroform and the disadvantages of ether are both largely diminished by putting the patient under chloroform till insensibility is produced, and then substituting ether to maintain the condition.

Nitrous Oxide, or **Laughing Gas,** is a colourless odourless gas, made by heating nitrate of ammonia. It is a compound of nitrogen and oxygen, and its chemical formula is N_2O. In ordinary circumstances it is a gas, but under pressure it is condensed to a liquid, and kept in strong iron bottles, whence it is allowed to escape for use into a gasometer. It must be inhaled pure without any admixture of air. When so inhaled it takes the place of oxygen in the blood, converts the arterial into venous blood, and as a result a condition, so far as the blood is concerned, resembling suffocation arises. The face becomes livid and bloated, and the breathing stertorous, and muscular twitchings begin to occur. These effects will be produced after about 1 minute's inhalation. The person is at this time completely unconscious, and minor operations, such as extraction of a tooth, &c., can be performed without pain. If the inhalation be stopped at this stage, recovery takes place, and in from $\frac{1}{2}$ to 1 minute all the symptoms named will have disappeared and natural breathing be fully restored. If the inhalation were carried beyond this stage, the action of the heart and of breathing would be arrested. After the immediate effects have passed away, the patient usually feels some degree of exhilaration, and his laughter is readily excited. If this gas be inhaled *mixed with air*, or if after the pure gas has been inhaled for a little, and before it has had time to produce unconsciousness it be stopped and air inspired, a high degree of mental excitement is produced; the patient exhibits an uncontrollable desire to laugh, dance, gesticulate; and sometimes the excitement ends with a fit of pugnacity. But this series of phenomena, on account of which the gas was called "laughing gas", only occurs when the gas is not administered pure, without admixture of air.

Bichloride of Methylene is obtained from chloroform by the action of nascent hydrogen. Its formula is CH_2Cl_2, that of chloroform is $CHCl_3$. So that one atom of chlorine (Cl) has been removed from chloroform, and for it has been substituted one atom of hydrogen (H). It is a colourless volatile liquid, resembling chloroform in smell. It acts very much like chloroform, though it is attended with less risk. It has not, however, come to be very widely used in surgical practice.

Bichloride of Ethylene, or **Dichloride of Ethidene,** is another anæsthetic which for its safety has been recommended as a substitute for chloroform. Its formula is $C_2H_4Cl_2$. It is a colourless thin oily liquid, with a smell like chloroform.

Bromide of Ethyl, Hydrobromic Ether, is prepared by the action of bromine upon alcohol in the presence of phosphorus. Its formula is C_2H_5Br. It is a colourless volatile liquid, of strong ethereal odour and sweet taste. It is said to be an agreeable and rapid anæsthetic, its effects passing off more quickly than those of chloroform, and sickness being less common with it. Its advocates have pronounced it safer than chloroform, though death has happened under its administration.

Iodide of Ethyl, Hydriodic Ether, is a similar preparation, iodine being substituted for bromine, and it also acts as a general anæsthetic. Its chief use is for spasmodic attacks, specially for spasmodic asthma. It is put up in small glass capsules, each containing 5 drops, the capsule being encased in cotton wool and silk. When the attack comes on the capsule is crushed between finger and thumb, and the vapour inhaled through the wool.

Tetrachloride of Carbon (CCl_4), a colourless thin oily liquid of aromatic smell. It produces great weakness of the heart, and is not used for general anæsthesia. It has been used as an inhalation to relieve hay-fever and neuralgic pains.

n

SECTION IX.—REMEDIES FOR EXTERNAL APPLICATION.

Antiseptics:

Carbolic Acid; Sulphocarbolate of Soda and Zinc; Resorcin;
Boracic Acid and Boroglyceride;
Permanganate of Potash—Condy's Fluid;
Iodoform; Perchloride of Mercury—The Comparative Value of Various Disinfectants;
Eucalyptus Oil; Terebene; Thymol; Menthol; Sanitas;
Chlorine Gas;
Burnett's Disinfecting Fluia.

Remedies which Cause Redness and Blister:

Mustard—Its Uses as Poultice, Footbath, and Emetic;
Turpentine; Ammonia Liniment;
Cantharides (Spanish-fly).

Stimulating Liniments, Washes, and Ointments:

Red Wash; Lotions of Zinc; &c.;
Ointments of Boracic and Carbolic Acids, Creasote, Mercury, Iodine, Iodoform, and Tar; Blue, Red, Yellow, and White Precipitate Ointments, Resinous and Sulphur Ointments, Chrisma Sulphur, and Zinc Ointment.

Applications for Bleeding—Styptic or Astringent Applications:

Borax and Alum, Catechu, and Oak Bark;
Hazeline and Matico.

Soothing Liniments, Washes, and Ointments:

Applications of Opium and Belladonna;
Aconite; Carron Oil;
Veratria; Conium; Gall; Acetate of Lead;
Glycerine.

Antiseptics.

Antiseptics (Greek *anti*, against, and *sepein*, to rot) are substances which arrest putrefaction or decomposition. This they effect by preventing the development of the minute organisms on which such decompositions depend. All this has been fully explained at the beginning of Section XII., Part I., p. 384. They are required for external use to prevent putrefaction occurring in wounds, and they are also employed to cleanse instruments, to wash the hands, &c., in order to prevent the conveyance of infective material from one person to another. It has been pointed out on p. 395, that while certain substances only prevent the development of such organisms, other substances absolutely destroy them, and that this latter process is true disinfection. Disregarding, however, such fine distinctions, we shall note in these paragraphs all the various substances employed for such purposes.

Carbolic Acid, Phenic Acid, Phenol, or Phenylic Alcohol, is an acid obtained from coal-tar by fractional distillation and purification. When pure it is in colourless needle-shaped crystals; and on the addition of 6 per cent of water it becomes and remains liquid. Its varieties as sold are as follows:—

No. 1 Carbolic Acid is pure acid, and is obtained in crystals, or with 6 per cent water as a liquid. One part makes a clear solution with 14 of water, and is best adapted for surgical or medical use.

No. 2 Carbolic Acid may be obtained as crystals or liquid. It makes a clear solution with 20 parts of water, is suited for surgical purposes and for the sick-room. 1 oz. in 2 pints of water may be used for sprinkling about.

No. 4 Carbolic Acid consists of 20 per cent carbolic acid and 80 per cent cresylic acid, and is used for disinfecting purposes, for drains, sinks, &c., for which it may be used of a strength of 1 oz. to 2 pints hot water.

No. 5 Carbolic Acid is a liquid adapted for stables, dust-bins, &c.

The preparations of carbolic acid are as follows:—

Glycerine of Carbolic Acid—Carbolic acid 1 oz., glycerine 4 ozs.

Carbolic Acid Ointment—Carbolic acid 1, soft paraffin 12, hard paraffin 6.

Carbolic Acid Lotion—Carbolic acid 1, water 19, or upwards.

Carbolic Oil—Crystals of carbolic acid 1, olive-oil 9.

Vapour of Carbolic Acid—20 drops of No. 1 liquid acid in a pint of water at 140° F.

Spray of Carbolic Acid—3 drops of No. 1 liquid acid in 1 oz. of water.

Carbolic acid is a true disinfectant as well as an antiseptic. In weak solutions it simply prevents the growth of organisms in stronger solutions it destroys them. One part in 40 of water is the strength usually employed for washing hands, and as a lotion for wounds. When it is applied, full strength, to the skin it produces

a white stain by destroying the immediate surface, and it greatly diminishes the sensibility of the part. It is frequently used of this strength to destroy foul ulcers, and as a paint for the throat in diphtheritic ulceration, and to apply to the skin in ringworm and other diseases dependent upon low forms of life, while the ointment is used to relieve itching diseases of the skin. The strong acid applied to the cavity of a tooth is one of the speediest remedies for toothache. It is best applied by a small fine camel-hair pencil, the hair being cut short. The cavity is brushed out several times with the brush soaked in the acid, the mouth being frequently rinsed with lukewarm water to remove excess of acid without burning the tongue and gums. The acid in weak solutions (1 to 40, or 1 to 30, or 1 to 20) is employed as a stimulating wash. Carbolic acid makes an excellent mouth wash along with tincture of myrrh and borax and glycerine. Take ½ ounce of each, mix, and make up the solution to 5 ounces with water. A small quantity of this, say about a tea-spoonful, in a wine-glassful of lukewarm water makes a most excellent mouth wash. It most effectively removes from the mouth the smell of tobacco smoke, and besides is an excellent preservative of the teeth and gums. In the form of the vapour, carbolic acid is used in bronchitis and other lung diseases attended by foul expectoration, and 1 part mixed with 3 of creasote may be used on Coghill's inhaler, as described on p. 882, in consumption. Common cold, beginning in the nostrils, is said to be much relieved by a douche of a solution containing 3 drops in an ounce of water, applied to the nostrils by means of a small ear-syringe, and to the throat as a gargle. It is even taken internally in cases of stomach disease attended by fermentative changes, being given in from 1 to 3 drops (No. 1 acid) largely diluted, to destroy the organisms causing the fermentation. Taken in large doses, or in strong solution, it produces the signs of irritation of stomach and bowels, vomiting and purging, and after absorption produces collapse, delirium, perhaps convulsions, and death. Giddiness, headache, lassitude, and unconsciousness also attend poisoning by the acid. Poisonous effects may arise owing to absorption from a large wound covered by carbolic acid dressings. The urine acquires a dark and even black colour from such absorption. In cases of poisoning by swallowing the acid, the stomach should be emptied by means of the stomach-pump or by emetics, then olive-oil should be administered, and thereafter 10-grain doses of sulphate of soda to aid its removal from the blood.

Sulphocarbolate of Soda, and **Sulphocarbolate of Zinc,** are formed from sulphuric and carbolic acid, with soda or zinc, as the case may be. The former is given internally in 10 to 15 grain doses to prevent fermentation in the stomach, and the latter is used in solution, 2 grains to 1 ounce of water, as a stimulating and antiseptic dressing for wounds with discharge.

Resorcin is a derivative of carbolic acid. It is used as a dressing for wounds and sores of all kinds in solutions varying in strength from 1 to 50 to 1 to 20 of water. It has been used in diphtheria as a paint to the throat, and an ointment made with ¼ to ⅞ oz. vaseline, applied to the face every 4 hours in erysipelas, is said to shorten the disease. A 1 per cent solution is a useful dressing for wounds. It is given internally, 5 grains with syrup of oranges and well diluted, to prevent fermentation in the stomach. It may be used for this purpose thrice daily before meals. It produces copious perspiration and has been employed to reduce fever of all kinds.

Creasote is a product of the distillation of wood-tar. Its dose and preparations are as follows:—Creasote—dose, 1 to 3 drops. Vapour of creasote (creasote 80 drops, light carbonate of magnesia 30 grains, water to 1 ounce), a tea-spoonful to a pint of water at 140° F. for inhalation. Creasote ointment, 60 drops to 1 ounce simple ointment. Creasote destroys low organisms and is employed for this property. Thus it may be used to stop toothache in a decayed tooth, as carbolic acid is used (see first col.). It is used in chronic bronchitis and in consumption to lessen cough and spit, either as vapour, or dropped on the lint of a Coghill inhaler (see p. 883), or it may be administered internally with cod-liver oil, 1 to 3 drops to each dose of the oil. The ointment may be employed as an antiseptic dressing.

Boracic Acid, or Boric Acid, is in the form of colourless, odourless plates, with a slightly bitter taste. It also is an antiseptic and is used for wounds and sores as a lotion, 1 oz. in 20 of hot water, or as an ointment. The ointment may be made of boracic acid in fine powder 3 ounces, paraffin melting at 135° 5 ounces, and vaseline 10 ounces, and is an excellent healing application. Boracic acid is largely used for the preservation of milk. The powdered acid, mixed with starch, is a useful dusting powder for infants; and the powder itself sprinkled in

the socks prevents the disagreeable odour of sweating feet.

Boroglyceride is a patented preparation made by heating 92 parts of glycerine with 62 parts of boracic acid. It is used as a preservative of meat, fish, milk, being used in solution for that purpose, 1 in 40 of water. It is also used as a surgical dressing.

Sulphurous Acid, a solution of sulphurous acid gas in water, is a powerful destroyer of decomposing material. This it effects by removing oxygen from the organic substance and thus destroying it. It is the gas which is liberated from burning sulphur, which is employed as a disinfectant. It is applied as a lotion, 1 oz. to 2 or more of water with the addition of a little glycerine, to ringworm, thrush, and as a spray in sore-throat. It is also given in doses varying from a few drops to a tea-spoonful, well diluted, in cases of vomiting dependent upon fermentation in the stomach.

Permanganate of Potash occurs as dark purple crystals, which readily dissolve in water to a pink solution. It is a substance which quickly destroys organic matter by giving off oxygen which unites with the organic substance. **Condy's red fluid** is a solution of the strength of 2 grains to the ounce of water. It is a powerful disinfectant, and will remove the smell from foul sores and destroy any foul smell on the hands. A few grains only need to be dissolved in the water and the hands well washed with it. It has been recommended for internal administration in cases of absence of the monthly discharge, being given in pill, 2 or 3 grains in each, three or four times daily for some days before the illness is due.

Permanganate of Soda in solution is also used as a disinfectant, and is a green solution.

Iodoform, a compound of carbon hydrogen and iodine, is a powder in shining lemon-yellow crystalline scales, with a very powerful and disagreeable odour. It is a strong antiseptic, but its own persistent and easily perceived odour renders it less desirable for use. The smell is covered by equal parts of it and Tonquin bean or by ground coffee. It diminishes the sensibility of the part to which it is applied. It is very useful as an application to foul sores, or to sores or wounds about the anus. It may be dusted on as a powder, or applied as an ointment, 1 in 4 or less of vaseline. As a snuff it is useful in common cold in the head. Made into suppositories, 5 grains in each, it is a most useful application to irritable and indeed all kinds of piles. It is occasionally administered internally, ½ to 3 grains in pill; and has been so employed with success in ulceration of the stomach. It may produce disagreeable effects on the nervous system, sleeplessness, headache, irritability, and loss of memory. These effects are said to be lessened be 10-grain doses of bicarbonate of soda or potash every hour.

Perchloride of Mercury Solution—Solution of Corrosive Sublimate (see p. 824). This is one of the most powerful of known antiseptics. Dr. Koch of Berlin, who has done more than anyone else in the way of systematic study of the causes of putrefaction and decomposition and the circumstances which favour or hinder their growth, has made a series of comparative experiments with the organism that is the cause of splenic fever (see p. 391), and various disinfectants. He found that a solution of

1 part of Carbolic Acid in	1,250	parts of water hindered the growth of the organism.
1 part of Boracic Acid in	1,250	,, ,, ,, ,,
1 part of Chlorine in	1,500	,, ,, ,, ,,
1 part of Eucalyptol in	2,500	,, ,, ,, ,,
1 part of Camphor in	2,500	,, ,, ,, ,,
1 part of Permanganate of Potash in	3,000	,, ,, ,, ,,
1 part of Oil of Cloves in	5,000	,, ,, ,, ,,
1 part of Peppermint Oil in	33,000	,, ,, ,, ,,
1 part of Thymol in	80,000	,, ,, ,, ,,
1 part of **Corrosive Sublimate** in	**1,000,000**	,, ,, ,, ,,

The enormous superiority of this antiseptic agent over every other in its destructive power is, therefore, apparent. One grain dissolved in one million grains of water still exerts its antiseptic power; and if the strength is increased threefold and made 1 grain in 300,000 the growth of the organism is not only hindered but totally prevented! One grain dissolved in 40 pounds weight of water is 1 in 300,000, that is in round numbers 1 grain in 4 gallons of water. It is, therefore, very extensively used as a disinfecting lotion to wounds, as a disinfecting uterine injection after child-birth, and to impregnate gauze, lint, cotton wool, prepared as dressing for wounds. The strength of solution employed for disinfection purposes varies from 1 in 1500 to 1 in 10,000. One grain dissolved in 10 ounces (½ pint) of water makes a solution a very little stronger than 1 in 5000. This can be used for disinfecting hands, for uterine in-

jection after child-birth, care being taken that it runs freely from the passage and is not retained. The author is accustomed to order such a solution in cases of scarlet fever for sponging the patient's body. The whole body is sponged daily, beginning a few days before the skin begins to peel, say on the sixth or seventh day of the fever, throughout the whole illness till all the peeling skin has been removed, that is to the end of the sixth week. After the sponging the body is lightly anointed with carbolic or other oil. In this way disinfection is achieved throughout the illness, and risk of the spread of the disease reduced to as little as it is possible.

Eucalyptus.—The *Eucalyptus globulus* or *Blue Gum-tree*, of the natural order Myrtaceæ, belongs to Tasmania. It was introduced into Europe in 1856, and has since been planted in the southern part of Europe, in Northern Africa, Southern United States, and California. It is a rapid grower, and attains a height of 200 feet. The leaves of old trees have a length of 6 to 12 inches, and have a strong camphoraceous odour; and they yield 6 per cent of a volatile oil, called oil of eucalyptus, or **Eucalyptol**. To eucalyptus the power of curing malaria has been ascribed, and the tree has been freely planted in malarious districts in the belief that it destroys malaria in the locality. It is undoubtedly a powerful antiseptic and disinfectant, and is used for surgical dressings. Internally it has been used in blood-poisoning, and in consumption, bronchitis with foul-smelling expectoration, and in catarrhal conditions of the bladder. It may be administered in doses of from 1 to 5 drops made into an emulsion with gum tragacanth and any flavouring syrup. It is removed from the body by the lungs and kidneys, and may thus exert upon them a special healing influence. A tincture of eucalyptus leaves may be made by steeping one part of the leaves in sufficient proof spirit to produce 5 parts of tincture, of which the dose is 15 drops to 2 tea-spoonfuls. This is a very suitable form of administration, and in lung affections may be added to cod-liver oil, the fishy flavour of which it removes. It may be used for inhalation with Coghill's inhaler (see p. 883); and 10 to 60 drops of a mixture of equal parts of the oil and rectified spirit are used as an inhalation in diphtheria.

Terebene is prepared from oil of turpentine by oxidation with sulphuric acid. It is used for inhalation as eucalyptol, and is also given internally in doses of 5 to 20 drops, chiefly in chronic bronchitis, and other lung affections, as it acts as a stimulant to the mucous membrane. It is sometimes used for flatulent distension of the stomach when the cause is fermentative changes in the food. It is a powerful antiseptic and deodorant.

Thymol is a crystalline substance obtained from the volatile oils of common thyme and other plants. It is a strong antiseptic (see p. 912) and disinfectant. When given internally it is expelled by lungs and kidneys, irritating their lining membrane. It is used in surgery, and is also employed as gargle in sore-throat, and as inhalation in lung affections. It is also employed for skin diseases, and a thymol soap is prepared. When given internally the dose is ½ to 2 grains and upwards, taken in pill with soap or in oily solution.

Thymol Lotion—for antiseptic purposes and disinfectant for sick-room, 1 part thymol in 800 warm water.
Thymol Ointment—5 to 30 grains to 1 oz. vaseline.
Thymol Vapour—6 grains thymol, 1 drachm rectified spirit, 3 grains carbonate of magnesia, water to 1 ounce. A tea-spoonful to 1 pint of water at 140° F. for inhalation in catarrh of air-passages.

Menthol, Peppermint Camphor, a white crystalline substance distilled from the fresh *Mentha arvensis* and *M. piperita*. It is a strong antiseptic. When rubbed on the skin it causes a burning sensation, replaced by a feeling of intense coldness if the part is blown upon. It is usually sold in the form of cones, **neuralgic cones**, for rubbing on any part affected with neuralgia, or the forehead for headache, &c. Liniment of menthol is made with 3 parts of menthol, 4 of chloroform, and olive-oil to 16, and is used for lumbago, neuralgia, and sciatica. Chinese oil of peppermint, called *Po-ho-yo*, Japanese Drops, or *Gouttes Japonnaises*, is sold in small bottles for the relief of neuralgia. It contains much menthol, from which it derives its properties.

Sanitas is a patent preparation, derived from turpentine, which owes its disinfectant properties to ozonic ether or peroxide of hydrogen.

Chlorine Gas is a greenish-yellow gas, with a suffocating odour. It is the active agent in bleaching powders, and is contained in the so-called chloride of lime, which is, properly speaking, chlorinated lime. This chlorinated lime is used for disinfecting properties, as it gives off chlorine slowly when exposed to the air. The vapour is heavier than air, and in order to permeate an apartment ought to be allowed to pass off nearer the roof of an apartment than the floor, for then it will sink and mix with the air of the room. The dish containing the chlorin-

ated lime should, therefore, be placed on a high shelf. Another method of obtaining it is to put a saucer containing salt, binoxide of manganese, and sulphuric acid on a high shelf; chlorine is evolved from the mixture. Another way is to make a strong solution of chlorinated lime, dip cloths into it, and hang them on a line stretched across the apartment near the roof. The cloths, it must not be forgotten, will be destroyed by the strong solution. Solutions of chlorinated lime or of chlorinated soda are employed to disinfect the hands or to disinfect wounds and ulcers.

Burnett's (Sir Wm.) **Disinfecting Fluid** is a solution of chloride of zinc of specific gravity 2.

Remedies which Redden and Blister the Skin.

One method of treating diseases continually employed in medicine is that by **counter-irritation.** This implies that when one part of the body is in a disturbed state, subject to pain, to threatened inflammation, &c., a neighbouring part is so acted on as to markedly irritate it and cause a rush of blood to it. That is to say, a temporary inflammation is aroused in the neighbouring part, and the disordered portion is in consequence relieved. The blood which is drawn to the place that is the seat of the counter-irritation is to some extent withdrawn from the threatened district. Thus when a mustard poultice is applied to the chest, so that the skin is reddened, the deep parts are relieved to the extent to which the blood attracted to the surface has come from the deep parts. Not only is the threatened part relieved by a diminished blood-supply, but it is believed that the irritation by nervous action will modify its activity and assist in the relief. There are various degrees of counter-irritation. By one set of remedies only a temporary redness of the skin is produced. These are called **rubefacients** (Latin *rubrum*, red, and *facio*, I make), and include hot water and hot applications, mustard, ammonia, camphor, vapour of chloroform, ether, turpentine, and various aromatic substances. The next degree of counter-irritation is that produced by a blister, a **vesicant** (Latin *vesica*, a blister); they are also called **epispastics** (Greek *epi*, upon, and *spao*, I draw). The chief of these is Spanish-fly or cantharides. Ammonia when long applied and confined acts thus, and iodine also. A third degree of counter-irritation is effected, when the remedy produces a crop of pustules, such as is produced by croton-oil. By the second and third degrees not only is a more profound effect produced at the time, but it lasts much longer, and its beneficial effect is thus maintained without further trouble.

Mustard.—There are two varieties of mustard —white and black, the former derived from *Brassica* (or *Sinapis*) *alba*, and the latter from *Brassica nigra* (p. 593).

A mustard poultice is prepared by mixing 2½ ounces of mustard with 2 or 3 ounces lukewarm water. Mix a similar quantity of linseed meal with half a pint of boiling water, then add the mustard mixture, stirring constantly. Where a less active poultice is desired, double the quantity of linseed meal may be taken.

Mustard paper is cartridge paper spread with mustard mixed with a solution of gutta percha. It should be immersed for a few seconds in tepid water before being applied, and should be well pressed down on to the skin. The Rigollot's mustard leaves are the form chiefly used. They act with great rapidity, reddening the skin with intense burning pain in 2 or 3 minutes. They need not be left on longer than 10 to 15 minutes, and even 5 minutes may be enough if they cannot be longer borne. In cases of persons with very delicate skin a layer or two of damped muslin may be placed between the leaf and the skin to make the action less violent.

A mustard foot-bath may be used as a general stimulant, for example, at the commencement of a common cold. In such a case the water should be as hot as can be borne, and two table-spoonfuls of mustard or thereby may be used. It may be used as a derivative, to draw blood from the head in head affections or from the lungs in chest affections. For this purpose the water should be only lukewarm.

A general mustard bath is sometimes employed. For children a table-spoonful of mustard should be added to the bath sufficiently large for the child, and the child held in it by the nurse's arms till they tingle. It is used in bronchitis, and in the fevers with rash where the eruption has not been well developed or has faded too soon. The water should be only lukewarm. For adults a general mustard bath would require from 2 to 3 ounces and upwards of mustard.

Mustard-oil is the oil distilled from the seeds of mustard after they have been steeped with water. It is used as a stimulating liniment and for similar purposes to mustard itself.

Compound Liniment of Mustard is made of oil of mustard 1 drachm, ethereal extract of mezereon 40 grains, camphor 120 grains, castor-oil 5 drachms, and rectified spirit 32 drachms.

This may be used simply as a liniment, or sprinkled on some material like spongiopiline or even flannel, and applied as a mustard leaf would be.

The Uses of Mustard.—Mustard poultices are employed in pleurisy, inflammation of the lung, bronchitis, &c., to withdraw the blood from the interior of the chest. For these purposes the larger the poultice the better, and while the risk of raising a blister is to be carefully avoided, the skin should in a short time be made quite red. The effect should be kept up for a considerable period, 24 hours or more, by a judicious reapplication of the poultice at appropriate intervals. If the poultice is properly made and put on warm enough to act quickly as it ought to do, two or three poultices in the 24 hours ought to be quite sufficient. A poultice ought not to be kept on longer than 15 to 20 minutes at a time. If it is properly made it can hardly be borne longer, and if it is properly made a 10-minutes' application ought to be sufficient. Many people apply poultices and no redness of skin is perceptible after even an hour. This simply means that the mustard has not been active, either because it is bad or because the essential oil has been driven off by too great heat, or from some defect in application. A blister produced by mustard is painful and slow to heal, and always to be avoided. If a blister has been produced carron-oil (p. 844) is to be applied, and later zinc ointment.

Vomiting is often speedily relieved by a mustard poultice over the pit of the stomach; a mustard poultice applied to the nape of the neck will often remove headache very speedily; and a mustard poultice or leaf applied to the small of the back is very effective in relieving pain in that region, to which many people are subject after a fatiguing day's work or excitement. Large mustard poultices over the belly are required in pain there, specially if inflammatory mischief is threatened.

A mustard foot-bath is useful in common cold (see above) in relieving headache, in procuring sleep, to remove excess of blood from the head, and is very serviceable in cases of painful monthly illness. When the illness is arrested or suppressed, a mustard sitz-bath, each day during the time the discharge is due, is of value. Flying mustard poultices, a large mustard poultice applied for a few minutes, here and there, on different parts of the body, on the chest, belly, thighs, &c., are useful as a general stimulant in rousing a person suffering from opium-poisoning.

For hoarseness, inflammation of the windpipe or larynx, a mustard poultice ought never to be applied directly over the front of the throat. Owing to the thinness of the tissues intervening between the surface and the interior of the throat, only increase of swelling and a greater degree of hoarseness or difficulty of breathing would result from the rush of blood to the part. Particularly is this the case in children. Therefore the poultice ought always to be applied lower down, at the root of the neck or the upper part of the chest in front.

A tea-spoonful of mustard in a tumblerful of water is the dose for emetic purposes (see p. 851).

Turpentine has been already discussed on p. 872. It is largely used as a stimulating application to relieve pain and inflammation in affections of the chest and bowels, in neuralgia, lumbago, sciatica, &c. A good method of applying it is to sprinkle the turpentine on a piece of flannel, sufficient being used to damp the flannel. This is applied over the part of the skin to be acted on. Above this is put a thick pad, made of several layers of flannel, wrung out of water as hot as can be borne. The whole is secured by a broad bandage. It is to be kept on till the skin is quite red, but short of blistering, and it will blister when the vapour is confined in this way, if it be kept on long enough. The part may then be dressed with a layer of cotton wool secured by a bandage, or with a sheet of lint moistened with olive-oil.

Ammonia (see p. 843), the spirits of hartshorn, is employed as a counter-irritant in the same way as mustard or blisters. It may be applied sprinkled on flannel or lint, and it reddens the skin in a few minutes, when it should be removed.

Liniment of Ammonia, "Hartshorn and Oil," is best suited for this purpose, 1 part of hartshorn and 3 of olive-oil. This also is applied in flannel or lint.

The strong ammonia may be employed to produce a blister as follows:—Cut a piece of lint a little longer than the desired blister. On this pad pour 10 or 20 drops of the strong solution of ammonia, apply to the skin and cover with a good-sized watch-glass. In a short time, when the skin has become quite red, the lint is removed and a poultice applied, which raises the blister in from ten minutes to half an hour. It is, however, not quite certain, the skin of some not being blistered by it. Spanish-fly is much more reliable, and for the mere production of redness mustard is better.

The liniment is, however, an admirable stimulating liniment for painful and swollen joints, for stiff joints, for rubbing over sprained parts after all acute pain has ceased, and for similar purposes.

Iodine is described on p. 825. The preparations employed for external application are the tincture, the liniment (made with 5 parts of iodine, 2 of iodide of potassium, 1 of camphor, and 40 of rectified spirit), and the ointment. There is also a preparation called colourless iodine, made with iodine and hyposulphite of soda, which does not stain the skin. If the skin is not too tender two coats of the liniment should be painted on with a camel-hair pencil; but if the skin is delicate one coat is enough.

It is painted on the back of the chest in chronic pleurisy to promote the removal of the fluid accumulated in the chest cavity; and it is advised to be painted on the front under the collar bones to relieve the harassing cough of consumption. For the relief of pain a mustard poultice is better. It may be painted round chronically swollen joints, but small frequently repeated blisters are more serviceable. It ought never to be used by unskilled persons to paint over swollen glands. If any pain and tenderness exist in the gland the chance of exciting inflammation and the formation of matter is great (see p. 209); and many children are permanently disfigured by such a result. The ointment well rubbed over chilblains, so long as the skin is unbroken, is often sufficient to effect a cure in two or three days.

Spanish-flies.—This is the dried insect *Cantharis vesicatoria*, belonging to the beetle order, Coleoptera. It is indigenous to Southern and Central Europe, frequents chiefly trees and shrubs, such as ash, lilac, elder, and honeysuckle. It is from ½ to 1½ inch long and ⅕ to ⅓ inch broad, and of a shining metallic green colour. The beetles are collected in early morning by shaking them off the trees into white cloths spread below. They are killed by immersion in hot water and are then dried. They are reduced to powder, which is greyish-brown in colour and contains shining green particles. The chief preparations are:—

Tincture Cantharidis.
Blistering Paper (Charta Epispastica or Cantharidis).
Cantharides Plaster—Blistering Plaster (Emplastrum Cantharidis or Lyttæ).
Blistering Fluid—Liquor Epispasticus.
Cantharides Ointment.

This blister when applied to the skin first reddens and then causes the production of a large bleb filled with fluid. The blistering action is due to an active principle called **cantharidin**. The blistering plaster is spread on leather or adhesive plaster in a layer about the thickness of a sixpence, and the surface is lightly touched with oil. If the skin over which it is to be applied is washed with soap and water and then bathed with vinegar, the plaster will act better. If only a slight degree of action is wanted the blister should be removed in three or six hours, and a piece of carded cotton applied to the part; if more energetic action is wanted it should be left for 12 hours, and dressed, after the raised skin is snipped through, with lint soaked in oil. The blistering paper is less energetic than the plaster. The blistering fluid is applied by painting it over a portion of skin the extent of the desired blister, and then applying several hot poultices.

It is scarcely possible to indicate here when a blister is suitable and when it is not. It is needful to say that blisters should never be employed at haphazard, specially large blisters. They are very often far too readily employed. Specially in the case of the young and the old must they be used with discrimination, if used at all, the risks of destroying the skin in mass are so considerable. It is to be remembered that a very considerable depressing effect is produced on a person by the action of a blister, both on account of the fluid withdrawn from the blood and by the effect on the nervous system. The weakening effect will be all the more pronounced the larger the blister is. As a general rule it may be said that if blisters are resorted to in the absence of skilled medical advice, it is better to apply small flying blisters than large ones, that is a small blister—varying from the size of a shilling to that of a crown piece—may be applied to a particular spot on one day, a second in its neighbourhood the next day, and so on, each being allowed to heal as quickly as possible. Such blisters are applied on the temple and at the back of the ear for inflammations of the eye and ear; they are applied round swollen joints to remove pain and swelling, as at the knee-joint, at the nape of the neck to relieve giddiness and head symptoms, over the heart to relieve pain there, over the pit of the stomach to relieve vomiting, down the spine to relieve spinal irritation, and on the painful spots of a nerve to remove neuralgia. A long narrow blister down the back of the thigh is often useful in sciatica. In acute rheumatism large blisters applied round the limb above and below the affected joint are strongly advocated.

If taken internally, Spanish-flies produce marked irritation of stomach and bowels, with vomiting and purging, as well as severe inflammation of the kidney and strangury. Very large doses produce delirium, spasms, stupor, and death.

The application of large blisters is liable in many people to produce marked signs of irritation of the kidneys and bladder. This is supposed to be prevented by sprinkling the surface of the blister with finely-powdered camphor or by painting it over with tincture of camphor.

The stimulating effect which cantharides has upon the skin is made use of to promote the growth of hair. **Erasmus Wilson's Hair Wash** consists of vinegar of cantharides 1 part, glycerine 1, tincture of bark ½, orange-flower water 8, and rose water 8.

Poisoning by Spanish-flies is to be met by emptying the stomach by an ipecacuanha emetic and then giving large draughts of gummy water, oil and spirit being avoided, as they dissolve the active principle. To relieve irritation of kidneys and bladder, warm sitz-baths and opium are advised.

Croton-oil has been sufficiently referred to on pp. 861, 862.

Stimulating Liniments, Washes, and Ointments.

Stimulating liniments or **embrocations** are specially employed to relieve stiffness after inflammation or injury, to remove thickening and swelling when all acute pain has passed, and to restore the full use of the part. As a general rule these liniments are not to be employed until all active inflammation has passed. Thus suppose a person sprains an ankle or a wrist, rubbing and the application of any stimulating material could only aggravate the pain. It is rest and soothing applications, such as warm cloths, that are desired, and when all the acute results have passed, then rubbing with a liniment, gently at first, and then, after trial has shown it to be quite safe, more vigorously, will remove the remaining swelling, get rid of the stiffness, and restore the full use of the part.

The chief stimulating liniments are:—

Arnica Tincture.
Hartshorn and Oil—Liniment of Ammonia.
Camphorated Oil—Liniment of Camphor.
Compound Camphor Liniment (camphor 2½ ozs., oil of lavender 1 drachm, strong ammonia 5 ozs., rectified spirit 15 ozs.).
Iodine Liniment.
Soap Liniment.
Soap and Opium Liniment—Opodeldoc.
Compound Mustard Liniment.
Liniment of Turpentine (turpentine-oil 16, soft soap 2, camphor 1; dissolve the camphor in the turpentine and then rub up with the soap).

Arnica is the root-stock of *Arnica montana.* This is used for the tincture, and there is also a tincture of the flower-heads. It is used for bruises and sprains, but should not be rubbed on till after all acute pain has ceased, as it is capable of setting up inflammation.

Stimulating lotions are for ulcers, wounds, &c., which are slow of healing because of a defective blood supply. The ulcer or wound of this kind is pale in colour, smooth on the surface, not covered over with the little sprouting granulations which every healing wound shows. The edges are thick, white, and not sensitive, and the discharge is thin and scanty.

The chief lotion for such cases is the

Red Wash (sulphate of zinc 16 grains, spirit of rosemary and compound tincture of lavender, of each 2 drachms, water to 8 ozs.).

Other stimulating lotions are:—

Black Wash (30 grains calomel, ½ pint lime water).
Yellow Wash (18 grains corrosive sublimate, ½ pint lime water).
Sulphocarbolate of Zinc (2 grains to 1 oz. water).
Corrosive Sublimate (1 grain to 1 oz. water).
Chloride of Zinc (2 grains to 1 oz. water).

Stimulating Ointments are as follows:—

Boracic Acid and Carbolic Acid Ointments.
Creasote Ointment (p. 911).
Blue Ointment.
Red Precipitate Ointment.
Yellow ,, ,,
White ,, ,,
Citrine Ointment.
Scott's Dressing.
Chrysophanic Acid Ointment.
Iodine, Iodoform, and Tar Ointments.
Resinous Ointment.
Sulphur Ointment.
Chrisma Sulphur.
Zinc Ointment.

The three ointments that head the list are stimulating and antiseptic ointments. The blue, red, yellow, and white precipitate, citrine ointments, and Scott's dressing, are all mercurial preparations. The first four of them are all used to destroy insects.

The **Red and Yellow Precipitate** ointments are specially useful in inflamed conditions of the eyelids, being applied at night, and as a stimulant to chronic inflammatory eruptions of the skin.

The **Citrine Ointment** is similarly used.

Scott's Dressing consists of strong blue ointment 6 parts, yellow wax, and olive-oil, of each 3, and camphor 1½. The camphor in fine powder is added to the melted wax and oil when nearly cold, and the blue ointment next. It is applied to chronically inflamed and swollen joints. The dressing is spread on a sheet of lint, which is then cut up into strips, these are wrapped round the joint, one overlapping the other till the joint is completely enveloped. Strips of adhesive plaster are then applied in the same way as tightly as possible, and over all a starch bandage is applied. In two or three weeks it is removed, and the swelling will usually be found greatly subdued. If owing to diminished swelling the application becomes loose, it should be removed and reapplied.

Iodine Ointment may be used like the liniment for stimulating purposes, and is very useful for chilblains.

Chrysophanic Acid Ointment is made with chrysophanic acid or chrysarobin 1 part, and benzoated lard 10 parts.

Chrysophanic acid is derived from Araroba or Goa powder, a concretion from clefts in the stem of *Andira Araroba*, a leguminous tree imported from Brazil. It is an orange-yellow powder.

The ointment is very stimulating to the skin, destroys low vegetable organisms in the skin, and is very successfully used in scaly diseases such as psoriasis, and in ringworm. It stains the skin and clothing. Clothing containing starch it colours blue; therefore linen or cotton should not be worn during its use.

Iodoform Ointment is employed for foul ulcers, indolent sores, and unhealthy wounds.

Tar Ointments are specially resorted to in skin affections, in eczema, psoriasis, ringworm, prickly heat, and specially to relieve ringworm.

Resinous or **Basilicum Ointment** is a popular dressing for indolent sores. It is made of resin or colophony, the residue left from the various species of pine after distilling off the oil of turpentine. Two parts of resin in coarse powder, 1 part of yellow wax, and 4 parts of simple ointment are melted together with gentle heat, strained while hot through flannel, and stirred till cold. Simple ointment is made of 2 parts white wax, 3 of prepared lard, and 3 of almond oil melted together and stirred till solid.

Sulphur Ointment is used in itch, in eczema, ringworm of the head, and many other skin affections.

Chrisma is a petroleum preparation like vaseline, and has the property of dissolving sulphur. In consequence chrisma sulphur is more active than the common sulphur ointment. It is specially valuable in eczema, specially when found in the head and face of children, to which it should be freely applied, after the scabs have been removed by diligent soaking with water, or after softening with a turnip poultice.

Zinc Ointment is the common white "healing ointment." The oleate of zinc ointment is preferable to the common zinc ointment. It is made of 1 ounce of oleate of zinc and 1 ounce of vaseline, and may be made weaker, ½ or ¼ oz. oleate to the ounce of vaseline. This form is easily removed from the sore or ulcer, and does not coat it with an irritating crust. Besides for ordinary wounds and sores, it is often useful in chronic eczema.

Astringent Lotions and Washes.

Astringents are applied to the surface of the body to cause contraction of the part, to lessen discharge, to give a tone to the part, to cause ulcers and wounds to take on a more healthy action, to diminish their size, and make the healing surface less flabby and soft. Used as eye lotions they diminish inflammation and the flow of matter, as gargles or spray they lessen the secretion of phlegm and strengthen the throat, and as injections to the genital passages or womb they are used to lessen congestion and discharge. The chief astringents have already been discussed on p. 867 and two following pages in connection with their internal use in diarrhœa.

Borax and Alum Lotions, 2 tea-spoonfuls of the former to a pint of water, a tea-spoonful of the latter to a pint are useful astringent injections.

Catechu Lotion is made with 60 grains catechu to 8 ozs. hot water.

Oak-bark Lotion requires 2 ozs. of the bark to 1 pint of water, boiled down to a half.

The stimulating lotions mentioned above are useful for similar purposes or for the bathing of wounds.

For use as a gargle borax may be used, 120 grains to 1 oz. tincture of myrrh and 8 ozs. water; or borax 120 grains in 1 oz. glycerine, used as a paint to sores of mouth and throat.

Alum may be used as gargle, 80 grains to 1 oz. tincture of myrrh and 8 ozs. water, or tannic acid 35 grains, tincture of myrrh 4 drachms, and eau de cologne 1½ ozs., for soft and sore gums.

Chlorate of potash ¼ oz., tincture of myrrh and borax ½ oz., glycerine 1 oz., and water to

4 ozs. make a useful gargle for ulcerated throat and mouth.

For Sprays to the Throat, sulphurous acid ½ oz. to 1 oz. of water, or an increased strength up to equal parts, dried alum 3 to 20 grains to 1 oz. water, tannic acid 3 to 12 grains to 1 oz. water, borax 5 to 20 grains to 1 oz. water, chlorate of potash 5 to 10 grains to 1 oz. water, tincture of steel 5 to 30 grains to 1 oz. water, sulphate of zinc 3 to 15 grains to 1 oz. water, may all be employed.

Applications for Bleeding. — When astringent substances are applied to arrest bleeding they are called **Styptics.** Alum, catechu and oak-bark, borax, and tannin can all be used for this purpose. Hazeline is an admirable remedy for this purpose, and a solution of 1 grain sulphate of iron to 1 oz. water.

Styptic Colloid is a preparation made by saturating alcohol with tannin and then adding ether and gun-cotton. When painted over the part it stops the bleeding and leaves the surface protected by a film.

Matico Leaves, the dried leaves of *Piper angustifolia* from Peru, are used to arrest bleeding from small wounds, such as leech bites. The leaf contains tannin, and an infusion is astringent. Of the infusion the dose internally is 1 to 4 ozs., of a fluid extract (American) ½ to 3 tea-spoonfuls, and of tincture the same.

Compound Tincture of Benzoin, or Friars' Balsam, is the popular application for bleeding wounds. It is not cleanly enough.

Soothing Liniments, Washes, and Ointments.

The **Soothing Liniments** are employed to relieve pain. They are:—

Liniment of Aconite.
,, ,, Belladonna.
,, ,, Lime (Carron-oil, equal parts of lime-water and linseed-oil).
,, ,, Chloroform.
,, ,, Opium.

The liniment of aconite is used in neuralgia and sciatica, rubbed along the course of the affected nerve, and for painful and swollen joints, and it is rubbed over muscles in muscular rheumatism. The liniment relieves pain by diminishing the sensibility of the part. Great care requires to be exercised lest some becomes absorbed and affects the general system (see p. 834). Belladonna liniment is similarly employed, and is often mixed with aconite liniment as well as with liniment of chloroform.

Carron-oil is the most soothing application for burns.

Liniment of opium or soap and opium liniment is used for painful swellings, lumbago, &c.

Soothing Lotions, &c. are:—

Lead Lotion, or Goulard's Lotion.
Opiate Lotion (30 grains powder of opium, 8 ozs. boiling water; strain after 2 hours).
Poppy Lotion (extract of poppy 120 grains, 4 ozs. boiling water).
Conium Lotion (60 grains extract of conium, 3 ozs. water).
Belladonna Lotion (20 grains extract of belladonna, 4 ozs. water).
Glycerine.

All these may be applied to irritable sores, sores which fail to heal from excess of action (see p. 366), and which are hot, tender, raw-looking, and painful. There is a thin acrid discharge, and they bleed on the slightest touch.

Soothing Ointments, which are used for similar purposes to the soothing lotions, are:—

Atropine and Belladonna Ointment.
Aconitia Ointment.
Gall and Opium Ointment.
Acetate of Lead Ointment.
Marsh-mallow or Althæa Ointment.
Veratrine Ointment.
Vaseline.
Lanoline.

The uses of these have been sufficiently indicated by what has been said above.

The aconitia ointment is not to be used without medical advice; its strength as a poison is so great.

Gall and opium ointment is not only soothing but astringent, and is used for piles.

The acetate of lead ointment is one of the most useful of these applications.

Veratrine ointment acts like aconite, diminishing the sensibility of the nerves of the skin, and is used for neuralgic affections.

Vaseline or Petroleum Ointment is a substance obtained by distilling off the lighter portions of American petroleum. It does not become rancid, and is a protection to all raw surfaces.

Lanoline is a purified fat obtained from sheep's wool. It may be used as vaseline or simple ointment is used. It is very largely used as a basis for ointments, since it is readily absorbed by the skin, and drugs mixed with it and rubbed on the skin enter the system much more rapidly than if mixed with ordinary lard or vaseline. **Agnine** is the term applied to a similar substance in America.

SECTION X.—MINERAL BATHS AND WELLS.

The Action of Pure Water on the Body.

The Action of Mineral Waters on the Body.

Classification of Mineral Waters:

Indifferent Waters—Thermal Springs;
Common Salt Waters—Simple Saline Waters—Muriated Saline Waters;
Bitter or Aperient Waters—Sulphated Waters;
Soda or Alkaline Waters;
Muriated Alkaline Waters—Soda Waters with Common Salt;
Sulphur Waters;
Lime Waters—Earthy or Calcareous Waters;
Iron Springs—Chalybeate Waters;
Iodine and Arsenical Waters.

Routine of Life at a Spa—Bath-fever.

Indifferent Waters—Thermal Springs—Wildbäder:

Acqui—Badenweiler—Bagnères de Bigorre—Bath—Bormio—Buxton—Gastein—Hammam Meskoutin—Hammam R'Irrha—Hot Springs (Arkansas and Virginia)—Johannisbad—Landeck—Leukerbad (Leuk, Lœche-les-Bains)—Liebenzell—Lucca—Luxeuil—Matlock—Neris—Neuhaus—Panticosa—Pfäffers—Plombières—Ragatz—Römerbad—Schlangenbad—Teplitz—Tobelbad—Tüffer—Warmbrunn—Wildbad.

Common Salt Waters—Muriated Saline Waters—Sool Baths:

Adelheidsquelle—Baden-Baden—Bex—Bourbonne-les-Bains—Canstatt—Cheltenham—Cronthal—Dipso or Aedepsos—Droitwich—Dürkheim—Hall—Heilbrunn (Adelheid Spring)—Homburg (Elizabeth Spring)—Ischia—Ischl—Iwonicz—Kissingen (Rakoczy Spring)—Kreuth—Kreuznach—Leamington—Mergentheim—Mondorf—Nauheim—Neuhaus—Pyrmont (Salt Spring)—Rehme Oeynhausen—Reichenhall—Saratoga (Empire Spring)—Schmalkalden—Soden (Nassau, and near Aschaffenberg)—Thermia—Wiesbaden—Wildegg—Woodhall.

Bitter Waters—Aperient or Sulphated Waters:

Aesculap—Bedford Springs—Bertrich—Birmensdorf—Carlsbad (Sprudel)—Cheltenham—Elster—Epsom—Franzensbad (Franzensquelle)—Friedrichshall—Füred—Hunyadi Janos—Leamington (Saline Spring)—Marienbad (Kreuzbrunnen)—Mattoni's Royal Hungarian Bitter Water—Mergentheim—Ofen or Buda—Püllna—Purton—Rohitsch (Tempelbrunnen)—Rubinat—Saidschütz—Scarborough Wells—Sedlitz—Stubuya—Tarasp (Great Spring)—Victoria-Ofner.

Simple Soda Waters—Alkaline Waters:

Apollinaris—Bilin—Desaignes (Eau de César)—Fachingen—Fellathal—Geilnau—Gerolstein—Gettysburg—Giesshübel—Kronenquelle—Mont Dore—Neuenahr—Preblau—Salzbrunn—Saint Marco—Soulzmatt—Vals—Vichy—Chaudes Aigues—Evian-les-Bains—Néris—Teinach.

Soda Waters with Common Salt—Muriated Alkaline Waters:

Birresborn—Ems—Gleichenberg—Kainzenbad—La Bourboule (Choussy)—Luhatschowitz—Roisdorf—Royat—Selters—Vic-sur-cère.

Sulphur Waters:

Abano—Aix-les-Bains—Aix-la-Chapelle (Kaiserquelle)—Allevard-les-Bains—Amélie-les-Bains—Ax—Baden (Austria and Switzerland)—Bagnères de Luchon—Barèges—Battaglia—Buffalo Lithia Springs—Builth—Burtscheid—Cauterets—Challes—Eaux Bonnes—Eaux Chaudes—Eilsen—Enghien—Grosswardein—Gurnigel—Harkany—Harrogate (old sulphur well)—Helouan—Heustrich—Kainzenbad (Gutiquelle)—Spring at Kreuth—Langenbrücken—Le Vernet—Llandrindod—Llanwrtyd—Lisdunvarna—Mehadia—Meinberg—Moffat—Nenndorf—Panticosa—Pystjan (Posteny)—Saint Sauveur—Schinznach—Stachelberg—Strathpeffer (upper well)—Töplitz Warasdin—Uriage—Weilbach—White Sulphur Springs (West Virginia, U.S.).

Lime Waters—Earthy or Calcareous Waters:

Alet—Bethesda—Buffalo Lithia—Chateldon—Condillac—Contrexéville—Couzan—Cransac—Inselbad—Johannisbrunnen—Leukerbad (Lorenzspring)—Lippspringe—Lucca—Poland Spring—Pougues—St. Galmier (Source Nouvelle)—Sulis—Taunus—Weissenburg—Wildungen.

Chalybeate Waters:

Iodine Waters.

Arsenical Waters.

Whey and Grape Cures.

Mineral Baths and Wells.

The chief purpose of this section is to mention all the chief natural mineral waters now so commonly resorted to for the improvement or preservation of health, and for the treatment of disease, to note the chief constituents of these waters, and the effects they are supposed to produce, and to indicate the diseases for which they are employed. Mineral springs and wells are now so numerous that it is impossible in the space at our disposal to devote even a few lines of consideration to each. The plan will, therefore, be followed of classifying them according to their chief constituents, which will be to some considerable extent also a classification according to their uses. All the springs and waters which are in use to any extent can thus be arranged in a series of tables, and only the chief of them will be selected for further remark.

Nearly all of the springs are employed for bathing as well as for drinking purposes. In Part II. Section V. p. 732, and subsequent pages, sufficient has already been said regarding baths, and no further special consideration need be given to that subject. The waters which are employed for bathing purposes will, however, be mentioned, and their manner of use indicated as we go along, though the chief object of the section is to consider their effects when imbibed. We must first give some attention to the general effects of water on the body.

The Action of Pure Water on the Body.—By pure water we mean here not water chemically pure, but such water as is ordinarily used for drinking purposes. The nature of such water has been already discussed in Part II. Section II. p. 634. We have seen that the human body consists of water to the extent of 61 per cent (p. 535). Water is necessary to chemical changes going on, and the water removed from the body in the breath, in the sweat, in the urine, and by the bowels is the vehicle, so to speak, by which are removed from the organism the waste products of the chemical actions going forward in the body necessary to continued life and activity. As a general rule, the more active a tissue is, the greater is the amount of water it contains; thus, while bone contains only 48½ per cent of water, the gray substance of the brain contains nearly 86. Within certain limits, therefore, an increase in the amount of water taken will lead to increased activity of tissue change. If we take, for example, the water expelled by the kidneys, we find that, corresponding to an increase in the quantity imbibed, there is an increase in the output by these organs. The water thus expelled is more dilute, contains less substances in solution than an equal quantity of such as was expelled when only an ordinary amount of water was being taken, but if the quantities be collected for 24 hours, it is found that the total quantity of solids removed by the more dilute urine is in excess of that removed by the more concentrated. In short the drinking of an increased quantity of water has caused the removal of more waste from the body. There is a like increase in the waste removed by other channels, the skin, for example. An increase in the quantity of water drunk also will increase the quantities of digestive juices secreted, and to some extent assist the digestion; in particular it increases the production of bile. There is no doubt of its value in the stimulus thus given to removal of waste from the liver, and in the relief thus afforded to that organ.

In the deliberate use of larger quantities than usual of water, there are three circumstances worthy of special attention: (1) the time when the water is taken, (2) the rapidity of drinking—the quantity, in other words, taken at a time, and (3) the temperature of the water. As regards the time, water is more quickly removed from the stomach and passed into the vessels going to the liver when the stomach is empty. On this account the morning, before breakfast, is the time usually chosen. As regards the quantity, if a large quantity is introduced into the stomach at a time, absorption is apt to be slow, and discomfort likely to be experienced. The waters should, therefore, be sipped slowly. The person after sipping one glass walks up and down some verandah or pathway, engaged in pleasant conversation it may be, and in ten or fifteen minutes takes a second glass, and so on till he has consumed an appropriate supply. If he is unable to take as large a supply as is desired at one time, a further quantity may be taken before the midday and afternoon meals. As regards the temperature, waters taken warm, as

near as possible to the temperature of the blood, are less stimulating to the stomach and bowels, but the warmth promotes their absorption, and conduces, therefore, to their action on the blood and distant organs. When cold waters produce a loaded feeling of the stomach, this will be overcome by slightly warming them. If the waters are taken with the intention of stimulating the stomach and bowels, not so much for the purpose of being absorbed into the circulation, they are best taken cold. Mineral waters taken, for example, for constipation are best thus, and simple cold water taken on an empty stomach in the morning is often sufficient to secure an aperient action. Ice-cold water, again, is a most pronounced sedative to the stomach, but it must be sipped only in small quantities. Hot water also is soothing, and useful in painful affections. Moreover it stimulates the liver, and is a powerful aid to the removal of bile from the liver, for which, as well as for its general calming effects, it is taken in the evening.

Now if we sum up all these numerous effects of simple ordinary water drunk in early morning at a spa—the cleansing effects on kidney and skin, the increased removal of waste products, the stimulus to increased tissue change, the stimulus to the stomach, the washing out, so to speak, of bile from the liver, the restoration of regular function to the bowels—and if we add to all these the complete change of air and of scene, the complete change of occupation, of habits, and of companions, the cessation of hurry and worry, and of the accustomed routine of daily duties, we can easily understand how rapidly beneficial may be a brief stay at a spa, especially to the worn-out man of business or professional worker.

It is due undoubtedly to the circumstances indicated that many spas have obtained their repute; for a large number of the waters, as we shall see, contain no more solids than does ordinary drinking water from lake or river, and they are, therefore, called **indifferent waters.** One ingredient the most of these waters possess, namely carbonic acid gas. Bubbling up from a deep subterranean source, they cannot fail to be charged with such gas, as we have already explained on p. 651. Its effect upon the stomach is largely a mechanical one. The gas given off from the liquid in contact with the stomach walls appears gently to stimulate the circulation in the walls of the stomach, while a soothing effect seems also to be produced on the nerves. Whether that be due or not to the chemical action of the gas, it is not possible to say definitely. It is certain that an aerated water is often retained in the stomach when other materials, plain water among them, are rejected. The stimulating effects of the escaping gas act also upon the bowel, and simple aerated water will frequently prove effectual in constipation when plain cold water, and even purgative mineral waters, have no effect.

The Action of Mineral Waters on the Body.—While many of the spa waters contain no more, and some even less, solids in solution than common drinking water, most of them contain considerably greater quantities of saline material, some of them so much that they cannot be used for drinking or even bathing purposes without dilution. Among the principal ingredients of mineral waters are the following:—

Common salt (chloride of sodium).
Chloride of potassium.
,, magnesium.
,, lime.
Carbonate of soda.
,, potash.
,, magnesia.
,, lime.
,, iron.
Sulphate of soda (Glauber's salts).
,, magnesia (Epsom salts).
,, lime.

Besides these there are phosphates, compounds of bromine and iodine, arsenic, aluminium, strontium, lithium, barium, silicon, fluorine, nitrates, &c., and besides oxygen, nitrogen, and carbonic acid gas, sulphuretted hydrogen, ammonia, and others. A great variety of substances is contained in many mineral waters; and chemists are now able to detect the presence of substances which exist only in infinitesimal quantity. The minute quantity in which many ingredients are present renders it unlikely that they have any effectual share in the action of the water when taken into the system. On the whole, the character and effects of any given water are usually found to depend upon the two or three ingredients which it has in greatest amount. So that when a chemical analysis is placed before one it is comparatively easy to determine what the action of the water is likely to be, and under what circumstances it is likely to be useful. It is true that while chemists can analyse a mineral water, and determine the quantities in which the various ingredients are present, they cannot manufacture a mineral water which will produce the actual benefits of the natural product. But it must be remembered that the best results from

the waters are produced at the springs, where a great many attendant circumstances exist which make for health, and that if the natural waters bottled and used at home are not nearly so efficacious as those drunk at their source, it is because of the absence of these other favouring conditions. Further, though the chemist can accurately enough determine to the fraction of a grain the amount of sodium, potassium, magnesium, calcium, chlorine, nitrogen, oxygen, &c., present in a water, he cannot tell with anything like absolute certainty in what manner the elements are combined. Though he knows to a nicety the quantity of chlorine, sodium, potassium, &c., present, it is on theoretical grounds that he determines how much of the chlorine is in combination with sodium as common salt, how much in combination with potassium as chloride of potassium, &c. Therefore arises the difficulty, indeed the impossibility, of producing an exact imitation. In spite of these circumstances it is possible to classify mineral waters according to their chief constituents. Such a classification will have the advantage of at least indicating the chief effects the waters are likely to have on the body.

Classification of Mineral Waters.

I. First of all are the waters which contain so little solids of any kind that the effects they produce are due simply to the pure water itself. These are called **indifferent waters.** They are mostly obtained from warm springs, and they are mostly charged with carbonic acid gas.

II. The next class is of those whose principal ingredient is common salt, chloride of sodium. **Common salt waters, simple saline waters, muriated saline waters,** are all terms for this class. Some of them are warm, some are cold; most contain carbonic acid gas in some quantity.

III. A third class contain as their chief ingredient Epsom or Glauber's salt, the sulphate of magnesia or soda. These are because of their chemical character called **sulphated waters,** because of their taste **bitter waters,** and on account of their action **aperient waters.** Some of them contain one or other of the salts named or both, and no marked amount of other ingredients. Others have also notable amounts of both common salt and carbonate of soda. Hence the latter are sometimes distinguished by being called **alkaline sulphated waters.**

IV. In another class of waters the chief chemical characteristic is due to the presence of carbonate of soda or potash. These are the **simple soda or alkaline waters,** resorted to because of their antagonism to acid, in acidity of stomach and bowels, in gout, &c.

V. Other waters whose chief ingredient is also carbonate of soda contain besides common salt with carbonic acid gas. They are therefore called **muriated alkaline waters.**

VI. Then there are the **sulphur waters,** characterized by the presence in solution of that foul-smelling gas, sulphuretted hydrogen, or other sulphur compounds, much resorted to in liver and skin affections, in rheumatism also and gout.

VII. There are waters whose chief ingredient is lime in the form of carbonate or sulphate, as well as magnesia carbonate. These are the chalky, earthy, or **calcareous or lime waters.**

VIII. **Iron or chalybeate waters** are those in which the quantity of iron present is such as to confer upon the water its chief value for states of poverty of blood (anæmia), &c.

Some waters contain iodine or bromine or arsenic in such quantity, though still minute, as in the estimation of some to be endowed with special properties, and to be worthy of being characterized as **iodine waters, bromo-iodine waters, arsenical waters,** and so forth.

In each of the classes named, omitting the first, the information as to the chief ingredient or ingredients supplied by the name is an indication of the effects the water is likely to have and the purpose for which it may be used, as will be shown in the consideration now to be given to each class.

Routine of Life at a Spa.—The mere drinking of the waters of a spa or the taking of a course of baths is not the whole, not even the half, of the spa cure. To the change of scene, to the freedom from business cares, of which we have already spoken, must be added the strictly regular habits of life, the return to natural modes of living, and the simplicity of diet, which are all essential parts of a proper course of baths or mineral waters at a health resort. No one, who visits such a resort for the restoration of health, thinks of carrying with him the highly elaborate and artificial habits of life out of which he can hardly extricate himself at home. The visitor first of all, on arrival at the spa, consults one of the local physicians who is well acquainted with the action of the waters of the place and knows how to employ them to best advantage in each particular case. He has laid down for his guidance careful rules as to the waters to be drunk, the baths to be taken, the diet to be employed, the exercise to be engaged in, and if he be a wise man he will follow out the directions to the letter. The usual routine is

something like the following:—The patient rises at 6 a.m. or earlier, and betakes himself to the spring not later than 7 o'clock. He drinks one glass of the water, and walks for 15 minutes; then he drinks a second glass and again promenades for 15 minutes. A third glass follows and is succeeded by another walk of 15 to 30 minutes or longer, the time taken to return to hotel or lodgings being counted as part of the time. He then rests for half an hour or so, passing the time in agreeable conversation or some light occupation. Breakfast is taken at 9 a.m., a simple easily digested meal, often, as at Carlsbad, nothing more than one or two light rolls and coffee, and it is frequently taken in the open air in the gardens of a *café*. A little time after breakfast a walk or pleasant excursion is the rule, terminating, at any rate, half an hour or more before dinner to permit of rest before the chief meal of the day, which is at 1 o'clock or half-past 1. The meal is varied enough, its exact character being, however, prescribed by the physician. In the afternoon a second course of water-drinking may be prescribed. If so, it is usually between 4 and 5, the first glass being followed by a 15-minutes' walk and a second glass by a walk of half an hour or more. At 7 p.m. or 7·30 a light supper is taken; and the visitor goes to bed not later than 10 p.m. These are the general rules; but, of course, they are subject to variations in accordance with the strength of the individual. Thus while, as a rule, the water is taken on an empty stomach in the morning, if a patient feels too feeble to do so and to take so much exercise without food, he is allowed, before going to the spring, a cup of bouillon, or a glass of milk, or a cup of coffee and a small piece of bread; and many patients add to the waters milk or whey.

Baths are most frequently taken between 11 and 12 o'clock, or between 2 and 4 afternoon, or as near to these hours as can be arranged so that the time for bathing be pretty nearly equidistant between the hours for meals.

At many of the principal spas a long covered way is provided in which patients may take the prescribed amount of walking exercise during wet weather, while the time is made to pass pleasantly by the playing of varied selections of music by the instrumental band, which is one of the invariable accessories of a popular resort. The band plays usually at the spring for an hour or two in the morning, and for a similar time in the afternoon or evening. At Homburg, to suit English habits, there is lunch at 1 or 1·30 p.m., and dinner at 6 or 6·30 p.m. The evening performance by the band begins at 7·30 p.m.; and when the weather is unsuited for out-of-door performance, it takes place in a well-appointed concert-hall. It may be added that a course at a spa is usually prolonged for from three to six weeks, but varies according to the requirements of each individual patient.

Well-fever or **Bath-fever** is a feverish condition which sometimes arises with excessive use of waters or unduly prolonged or too hot baths. Giddiness, drowsiness or sleeplessness, a feeling of cold followed by heat and sweating, rashes on the skin, are some of the symptoms produced, which at one time were regarded as part of the necessary result of the treatment, and the indication of the system being affected by the treatment. Concerning this Braun says: "From the misuse, both as to quantity and temperature of waters taken medicinally, there result in many cases various conditions of indisposition, differing according to the individual concerned, and most unsuitably comprised under the mystical common designation of well-fever. A well-fever does not exist, any more than does a well spirit; and what is generally understood by the term are individual conditions, in consequence of a lasting or transient exaggerated effect produced by the method, diet, and new mode of life, often, of course, combined with excitement of the system, but without common, characteristic, and constant symptoms. Deluging the stomach with water very easily produces dyspepsia and catarrh of this organ; and the special peculiarities of the liquid, its cold or heat, and the different salts and gases contained in it, heighten and modify this influence; digestion suffers, nutrition fails, the skin is subject to various eruptions, especially boils, and from the general state of health the symptoms of the general malady are increased." Waters which contain little or no salts in solution produce such symptoms as readily as strong waters, if their employment is overdone. They are very frequently observed at Buxton and Gastein, whose waters are even purer than ordinary drinking water. These are the reverse of desirable results, and are to be avoided by medical advice being sought and followed in the use of the waters.

I. Indifferent Waters (Simple Thermal Springs—Wildbäder).

There are waters termed indifferent because they possess no particular chemical characters because of absence of solid constituents in any quantity. Some are even purer than ordinary lake or river water, used for drinking purposes.

They are perfectly transparent, and devoid of taste. These waters are very largely used for bathing purposes, the constant supply of hot or warm water from the spring being taken due advantage of, swimming baths being arranged as well as sitz and foot baths, &c. It does not appear that they have effects beyond those due to the warmth of the water. Many of them contain gases in solution, and the escape of the gas in the water is accompanied by a gently stimulating action on the skin. Most of these springs rise at considerable elevations in hilly regions, and on that account have been called wild-baths (Wildbäder), *Aquæ Ferinæ* or *Thermæ Silvestres*, and the mountain climate is to be taken into account in estimating their effects. The waters when drunk have the effects of pure water already described, and they may be taken as hot as possible from the spring or may be allowed to cool.

Such waters are used as baths for their calming and soothing effects, and are found beneficial in nervous cases, cases of neuralgia, hysteria, excitability of the nervous system, sciatica, and painful menstruation. In rheumatic affections and in gout, specially in irritable forms, their soothing effects and their influence in aiding the removal of thickenings and swellings are valuable. But this is not an exclusive property of this kind of bath. In skin affections they are prized. They are employed also in abdominal affections, such as are accompanied by chronic thickenings finding much relief from such treatment. In some forms of paralysis, such as that following diphtheria or consequent upon lead-poisoning, they often produce benefit. Such waters are taken internally to soothe irritability of stomach and bowels, to stimulate the action of the liver and promote the secretion of bile, to correct acidity of the stomach and constipation. In general states of ill-health and in retarded convalescence the waters are useful because of the promotion of tissue change, and the warm baths aid their action. Such baths and waters are also useful to persons who, not suffering from any organic disease, are exhausted and their vital powers lowered by excessive work or the fatigues of ultra-fashionable life. In such cases the well-directed life of the bathing establishment, with its regularity, its quietness, its mountain air, and the calming influences of the warm bath on the nervous system, and at the same time its gently stimulating effects on the skin and circulation, with the change of tissue it promotes in association with the drinking water, are all well adapted to promote a restoration to ordinary healthy activity.

The table No. I., page 926, contains the names of the chief springs whose characters have just been described, their situation, elevation above sea-level, and the temperature of the springs being also noted.

We must now give a few details regarding the more important of these springs.

Bagnères de Bigorre (1850 feet), on the Adour, in the Hautes Pyrénées, is included among the indifferent waters, since it contains barely 10 grains of solid constituents in 16 ounces, of which nearly 6 consist of sulphate of lime, not absorbed if the water is imbibed. It is one of the most popular baths in France. It possesses no less than twenty-four springs, two of which, the Foulon and the Salut, are used for bathing purposes to diminish excitability of the nervous system. Three of the springs contain carbonate of iron, nearly $\frac{2}{7}$ grain in 16 ounces in one of them, these waters also being at a high temperature. These are used in cases for which iron is suitable (see p. 947). The accommodation is good, and the situation beautiful. It is reached in $5\frac{1}{2}$ hours from Bordeaux.

Bath, in the county of Somerset, England, was at one time a most popular and fashionable resort, and after a period of neglect efforts are being made to restore it to something like its old estate by the provision of every possible aid to the comfort and pleasure of visitors. It has four springs (swimming bath 88°, king's 110°, queen's 112°, hot 118°). The waters are practically indifferent, containing barely 18 grains of solids to the pint, of which 10 are sulphate of lime, $2\frac{1}{2}$ sulphate of soda, $2\frac{1}{2}$ chlorides of sodium (common salt), and of magnesium, and $1\frac{1}{3}$ carbonate of lime. A minute quantity of oxide of iron is also present. The waters are recommended for rheumatism and gout, chronic skin diseases, as psoriasis and eczema, dyspepsia, and neuralgia; of the water $\frac{1}{2}$ to 2 tumblerfuls are taken once or twice daily. The advantage of Bath is that it is available the whole year. It affords, indeed, one of the best winter climates in England, and is resorted to rather between November and April than in summer, when it is too relaxing. Its disadvantage is that it is a large town of about 52,000 inhabitants, but the accommodation is in consequence of a wider variety, and its bathing establishments are good.

The mineral water of Bath is bottled for use as a table water under the title **Sulis**.

Buxton, in Derbyshire, England, at an elevation of 1000 feet, has an abundant supply of very pure water, containing only $2\frac{1}{4}$ grains of

solids in 20 ounces of water, with ½ cubic inch of carbonic acid gas, but 60 of nitrogen. Its air is pure and bracing, but the temperature is very variable, and the rainfall rather excessive. The water is chiefly used for bathing, five minutes' immersion in the natural bath, fifteen minutes' if its temperature is artificially raised to 93° or 96°. In chronic gout and rheumatism, especially with debility, it is most useful. Of the water 2 or 3 pints are drunk throughout the day, part an hour before breakfast, the rest early in the afternoon. Buxton is not a very desirable place for the very enfeebled or delicate. The risk of catching cold, owing to the variableness of the climate is considerable; and the hilly character of the situation does not admit of any extent of level walk for the real invalid. The season is from April to November.

I. SIMPLE WARM WATERS (THERMAL SPRINGS).

Name.	Situation.	Temperature in Degrees Fahrenheit.	Elevation in Feet.	REMARKS.
Acqui	Italy	103 to 113 and upwards.		Mud-baths also.
Badenweiler	Baden	69 to 81·5	1,425	Whey-cure also.
Bagnères de Bigorre	France (Pyrenees)	90 to 95	1,850	
Bath	England	88 to 118	100	Contains ·03 gr. oxide of iron in 20 ozs.
Bormio	Italy	90 to 104 and higher.	4,300	Season, May to September. For chronic rheumatism and hysteria. Via Innsbruck, Bozen, Meran, and Stilfserjock.
Buxton	England (Derbyshire)	82	1,000	
Gastein	Austrian Alps	96·8 to 114·8	3,315	
Hammam Meskoutin	Algeria	115 to 213		Season, May to October. For rheumatism, gout, malaria, skin-disease, and old gunshot wounds.
Hammam R'Irrha	Algeria	Hot.		
Hot Springs	Arkansas (America)	93 to 150		
Hot Springs	Virginia ,,	78 to 110		
Johannisbad	Bohemia	86	2,000	
Landeck	Glatz in Silesia	66 to 84	1,400	Season, May to October.
Leukerbad (Leuk, Lœche-les-Bains)	Switzerland	102 to 122	4,600	
Liebenzell	Wurtemberg	71·5 to 77	1,113	Contains $\frac{1}{10}$th gr. carbonate of iron.
Lucca	Italy	100 to 129		Season, June to Sept. For chronic rheumatism and skin-diseases. Contains 7 to 13 grs. sulphate of lime.
Luxeuil	Haute-Saône (France)	65 to 133	1,300	
Matlock	England (Derbyshire)	68		
Néris	France	114 to 125	800	For neuralgia, hysteria, rheumatism, and uterine complaints.
Neuhaus	Styria	95	1,200	Whey-cure pursued here also. Season, May to October.
Panticosa	Spain (Pyrenees)	77 to 92	5,000	The highest bath in Europe. A resort in consumption. Season, July to September.
Pfäffers	Switzerland	100.4	2,115	
Plombières	France	66·2 to 143·6	1,310	
Ragatz	Switzerland	100·4	1,510	
Römerbad	Styria	94 to 98	750	Near Tüffer. For hysteria and chronic uterine disease.
Schlangenbad	Nassau (Prussia)	86 to 90·5	900	Mud-baths also employed here.
Teplitz	Bohemia	99·5 to 108·5	648	
Tobelbad	Styria	77 to 83	1,200	
Tüffer	Styria	95 to 102·2	712	Akin to Schlangenbad and Römerbad. Whey-cure also.
Warmbrunn	Silesia (Prussia)	96·8 to 104	1,100	
Wildbad	Wurtemberg	93·2 to 102·2	1,323	

Gastein (3315 feet) is the chief German spa of the kind we are at present considering. In the Tyrol, thirteen hours' drive from Salzburg, in the midst of mountain scenery, it possesses a high reputation for its bracing climate. Rain is heavy in June, July, and August, and the temperature is variable though never very high, the highest being 86° Fahr. The most appropriate season is from the middle or end of July to the beginning of September. The water contains only 2½ grains of solids in 16 ozs., of which 1½ grains are sulphate of soda, so that it is a very soft water. Its high altitude allows the water to be used for bathing at a higher temperature, less excitement being produced than the same heat of water would cause at a lower elevation.

The duration of the bath varies from ten minutes to an hour, and it is suited for chronic rheumatic and gouty conditions especially in nervous and irritable subjects. Gastein has also a reputation for hysteria, some forms of paralysis and impotence. At **Hof-Gastein**, 500 feet lower, and an hour's distance by the road, more accommodation is obtained, and thither the water is conveyed.

Leukerbad (4600 feet) is situated at the foot of the Gemmi Pass in the canton Wallis, and is reached by a railway journey of six hours from Geneva and a road journey of three hours. The waters are classed as indifferent, though they contain 14 grains of solids to 16 ounces; of which, however, 10½ are sulphate of lime, and 2½ are sulphate of magnesia. The baths are employed chiefly in chronic skin disease, the duration of the bath extending from half an hour to eight hours. The bathers are attired in woollen mantles and capes, and pass the time in the bath playing dominoes and chess, taking luncheon, &c., on boards floated to them. Both sexes bathe together, chiefly Swiss and French. The season is from June to September.

Matlock, in Derbyshire, England, has water of a temperature of 68°, but is chiefly famous for its hydropathic establishment, where the system of bathing with hot and cold water is carried out in a scientific manner, probably unsurpassed anywhere.

Pfäffers and **Ragatz,** in the Swiss canton St. Gall, are an hour's walk from one another. The latter is a station on the railway from Rorschach to Chur, on the way to St. Moritz. The waters of Pfäffers are conveyed to Ragatz in wooden pipes. They are used for both bathing and drinking, and are adapted for nervous affections in women, for gout and rheumatism.

Plombières (1310 feet) is situated in the department of the Vosges south of Nancy, and distant from it four hours by railway, and is in France what Teplitz is in Germany. The waters are drunk to the extent of five to six glasses, are easily borne by the stomach, and are useful in chronic catarrh and painful conditions of that organ. The bathing establishments are commodious, and the surroundings in the way of scenery and amusements are pleasant and cheerful. Rheumatism, chronic joint affections, neuralgia, are also treated. Hot baths continued for some hours are used.

Schlangenbad (900 feet) is situated in a valley of the Taunus. Its railway-station is Eltville, and it is near Wiesbaden and Schwalbach. "It is one of the places best suited for the mild, soothing, and refreshing effect of thermal treatment" (Braun). "It is as picturesque as a place can be on the small scale, with shady alleys and endless forest paths. The baths . . . are beautifully arranged, and I can vouch for their pleasant feeling, though I leave it to the fair sex to vouch for their cosmetic properties. They have a great reputation for quieting and strengthening the nervous system, and are resorted to very much by hysterical ladies, and ladies suffering from functional derangements of the uterine system. Skin complaints are also treated here" (Macpherson). The season is May to October.

Teplitz (648 feet) is on a branch from the railway between Dresden and Prague. It is one of the most frequented baths in Europe, and with its newer suburb of **Schönau** affords a total of 4000 baths daily. The town, which is situated in a broad and pleasant valley, surrounded on all sides by hills, has a population of 16,300; its climate is mild, vegetation is luxurious, and the neighbourhood abounds in interest. The springs are numerous, the chief one containing scarcely 5 grains in 16 ounces, of which 2½ grains are carbonate of soda. The baths are given as hot as can be borne, and are employed for all such purposes as have already been indicated on p. 924—rheumatism, gout, &c.—and have a special reputation for old gunshot wounds. They sometimes induce a feverish condition, attended by skin eruptions (see Bath-fever, p. 924). Mud or moor or peat baths are used here also. The season begins in May.

Wildbad (1323 feet), lies in the Black Forest, south of Carlsruhe, and distant from it a railway journey of two hours. It lies in the pine-clad ravine of the Enz; and has a population of 3200. It "has almost everything that can recommend a place to the English." It can be reached from London by Paris and Strasburg in twenty-four to thirty hours. The accommodation and bathing arrangements are excellent. It also, like Teplitz and Gastein, may be taken as a type of the thermal spring, in its effects in rheumatism, gout, depressed conditions of general health, and so on. Various kinds of paralytic cases are specially to be found here. **Liebenzell** is within 8 miles of Wildbad, and **Teinach**, also with mineral springs, cold, one of which contains iron, is 15 miles distant.

Among other places which possess springs, which contain so little solids as to be fitly included among the class of indifferent waters, are **Clifton**, in Gloucestershire, England, whose water con-

tains 4½ grains to 16 ozs., and is of a temperature of 74° Fahr.; **Mallow**, in Ireland, with water of 69°; **Malvern**, in Worcestershire, England, whose water is pure but cold, and used in painful affections of kidneys and bladder; and **Bristol**, with hot wells (80° Fahr.), whose water contains 5¾ grains to 16 ozs., chiefly sulphate of lime and soda, and over 3 cubic inches of carbonic acid gas.

II. Common Salt Waters (Muriated Saline Waters—Sool Waters).

The waters to be considered under this head are those whose chief constituent is common salt, chloride of sodium, a compound of chlorine with sodium. Similar compounds with potassium, magnesium, and calcium (lime) also occur, the chlorides of potassium, magnesia and lime, but it is the sodium salt that is the most important. Waters rich chiefly in this ingredient are used both for bathing and for drinking purposes. Baths containing this ingredient are in Germany called **sool-baths** (sool-bäder). The chief effect upon the skin is a stimulating one, much more stimulating than simple water. It is for this purpose that sea-bathing is employed in the case of scrofulous children, and others with defective nutrition. The strong stimulating effect upon the skin not only exerts a bracing and tonic effect upon it by improving the circulation in it, but has a secondary effect upon all the functions of the body, quickening their activity and promoting tissue change. The pronounced effect of the addition of salt to water is shown by the fact that a bath which contains salt will have as strongly stimulating an effect upon the skin as much hotter water containing no salt in solution. Waters too rich in this ingredient may stimulate to an excessive degree leading to irritation. The exact degree of stimulation is determined by the quantity of salt in solution, the duration of the bath and its temperature. It appears that 2 to 3 per cent of salt is sufficient, that is 150 to 300 grains of salt in 16 ozs. of water, and that 10 per cent is too strong, and that a salt bath of 95° Fahr. will be as stimulating as one of plain water at 100°·8. When the natural water of the spring is too strong it is diluted, and when too weak it is strengthened by the addition of concentrated waters. When such waters are taken internally they stimulate the walls of the stomach and bowels, and if excess be taken the stimulation passes into irritation, evidenced by vomiting and perhaps purging, and other signs of catarrh of the stomach and bowels. But the waters have far wider effects than these. It must not be forgotten that salt exists in every organ and tissue of the body, and in every fluid and secretion or excretion (see pp. 535 and 541). About 3000 grains are present altogether in the body, 300 of them being ever in a state of coming and going, being expelled from the body with urine, sweat, &c., and being restored with food. Salt appears to have a very powerful influence in promoting the digestion and absorption of certain foods, and in the blood and tissues its presence seems to promote the activity of tissue change. At any-rate an increase in the quantity of salt introduced is soon followed by an increase in the amount of urea expelled, the result of the change albuminous food-stuffs undergo in the body (see p. 539). In a case where no common salt is introduced, it yet continues for a long time to appear in the urine, as if change could not go on without it, and the tissues could store up an extra quantity in case of need. Again, the absence of salt from the food or its presence in deficient quantity leads to serious disturbances of general health. A very important part in nutrition is also played by the chloride of potassium. By experiments with animals it has been shown that the absence of the latter from food, though the former be present in abundance, will be evidenced by feebleness and emaciation of the animal.

These facts are partly explanatory of the circumstance that the drinking, in appropriate quantity, of salt waters will greatly improve the nutrition of the body by its stimulating effects on tissue change. Thus such waters are used for this purpose in gout and scrofula. They are often effective in bloodlessness in women, when iron treatment has failed, and they also aid the absorption of iron. In general ill-health, the result of exposure to malaria, they have often proved useful, and in retarded convalescence from acute disease. Their stimulating effects upon the secretions of stomach and liver and other digestive organs are the cause of their extensive use in dyspepsia, both acute and chronic. For this purpose they should be taken cold, and in such quantity that from 60 to 300 grains of salt are introduced in this way daily. The carbonic acid gas they contain assists in producing the effect. In sluggishness of liver and bowels their employment is attended with benefit, as well as in other congestive disorders of other organs, such as the womb. Some of these waters are famous in the treatment of diseases peculiar to women, notably Kreuznach, and in England Woodhall. In both these waters

II. COMMON SALT WATERS (MURIATED SALINE WATERS).

Name.	Situation.	Altitude in Feet.	Quantity of Common Salt in grains in 16 ounces.	Quantity of Carbonic Acid Gas in cubic inches in 16 ounces.	Temperature of the Water in Degrees Fahr.	Remarks.
Adelheidsquelle	See Heilbrunn					
Baden-Baden	Black Forest	616	14½	1½	114·8 to 154·5	Contains also 2 grs. lime and traces of arsenic and bromine. Season, May to October.
Bex	Vaud (Switzerland)	1400				Grape-cure establishment.
Bourbonne-les-Bains	France (Vosges)	900	46	18	115 to 147	6 grains lime sulphate.
Canstatt	Würtemberg	600	16 to 19	19 to 27	63·5 to 69·1	Contains also ¼ gr. carbonate of iron, and 14 grs. lime salts. 4 miles from Stuttgart. Mud-baths and whey establishment.
Cheltenham	England		74·5		Cold	
Cronthal	Germany (nr. the Taunus)	500	22 to 27	33 to 40	56·7 to 61·2	Contains also 5 grs. lime salts and a trace of iron.
Dipso or Aedepsos	Greece (Negroponte)		68	2	88 to 162	Also ½ cub. in. sulphuretted hydrogen, 7 grs. of Epsom and Glauber's salts and iodide and bromides.
Droitwich	England,		2·500		Cold	
Dürkheim	Bavaria (foot of Haardt Mountain)	358	71 to 79	4 to 5	Cold	Grape and whey cure establishments. Contains 15 grs. lime salts and ¼ gr. iron, and iodine and bromine compounds from $\frac{1}{10}$th to $\frac{3}{10}$th grain.
Hall	Tyrol	1700	112	2	Cold	Contains iodine and bromine compounds to nearly 1 grain and a minute quantity of iron. Great repute in scrofulous goitre. Season, May to October.
Heilbrunn (Adelheid Spring)	Bavaria	2400	38	13	Cold	Contains nearly 1 gr. iodine and bromine compounds, and $\frac{7}{100}$th iron, and 6 grs. carbonate of soda.
Homburg (Elizabeth Spring)	Central Germany (Taunus)	600	48 to 104	43 to 109	50	Contains 17 grs. lime salts, ⅛th gr. iron. Season, May to September.
Ischia	Island, 20 m. from Naples					Season, spring and summer. Whey-cure.
Ischl	Austria	1400	223			Whey establishment and mud-baths. Season, May to September.
Iwonicz	Galicia		47 to 60	30	Cold	Contains also 8–13 grs. carbonate of soda, and small quantities iodine and bromine. Used as the waters of Kissingen.
Kissingen (Rakoczy Spring)	Bavaria.	590	17½ to 44½	41	Cold	Season, May to September.
Kreuth	Between Munich and Salzburg	2911				Salt springs used for baths for irritable and scrofulous subjects. Sheltered situation and still atmosphere. Whey-cure establishment.
Kreuznach	Rhen. Prus.	286	57 to 108	0	Cold	Season, end of April to beginning of Oct.
Leamington	England		40 to 60	2 to 3	Cold	Contains also from 32 to 40 grs. Glauber's salt, 20 chloride of lime, and small quantities of iron, bromine and iodine. (See table, p. 934.)
Mergentheim	Würtemberg	590	51	13	Cold	Contains small quantities iron, 15 grs. Epsom and 21 Glauber's salts, and 10 grs. sulphate and carbonate of lime.
Mondorf	Luxembourg	600	67	1	77	Contains 12 grs. indigestible sulphate of lime, and 24 of chloride, and ·002 arseniate of soda.
Nauheim	Hesse-Darmstadt	450	109	15	72	Contains 11½ grs. bicarbonate of lime, and ·2 carbonate of iron, ·004 arsenic, ·3 bromide of magnesium, and 8 chloride of lime. Other stronger springs used for bathing.
Neuhaus	nr. Kissingen	700	76	33		
Pyrmont (Salt Spring)	Waldeck	404	54	23	Cold	Contains also sulphate of magnesia 7 grs., sulphate and carbonate of lime 16 grs. (For iron springs at Pyrmont, see Table VIII.) This spring is suited for drinking.
Rehme Oeynhausen	Westphalia (betw. Minden and Cologne)	134	240	18	80 to 93	Very fine modern baths, gas baths, &c. Waters too strong for drinking. 22 grains lime sulphate.
Reichenhall	Bavaria	1407	23 per cent		57	Strongest salt spring in Europe used for bathing. For drinking 1 to 1½ oz. in glass of water. Whey establishment. Has an inhaling chamber, air impregnated with salt spray, useful in catarrh of chest and stomach. 32 grains lime sulphate.
Saratoga (Empire Spring)	U.S.A.		50½	34½	Cold	
Schmalkalden	Hesse	1000	71	8	Cold	Contains also 22 grs. lime sulphate, making it less suitable for drinking. Mud and pine baths.
Soden	Nassau (Taunus)	446	18 to 117	30 to 48	Lukewarm	Whey cure.
Soden	Near Aschaffenberg	440	40	0	Cold	The spring for bathing contains 160 grs. salt in 16 ounces.
Thermia (Island)	Greece		51½	3	116	Contain also bromine and iodine and 9 grs. Epsom salt.
Wiesbaden	Nassau	323	52½	6½	156	
Wildegg	Switzerland	1100	75			13½ grains sulphate of lime make it indigestible.
Woodhall	Lincolnshire, England		120			Contains ½ gr. bromide and ¼ gr. iodide of sodium.

there is present a small quantity of iodine or bromine or both, and to it the curative effects have been attributed. It is generally believed, however, that the undoubted benefits of such waters in inflammatory and congestive conditions of the uterine organs are the result of the stimulating effects of the salt water and not of the minute quantities of the other ingredients, and we shall, therefore, include them in the present group. By virtue of their stimulating tissue change they aid in removing enlargements from joints and from other parts of the body where inflammation has been accompanied by thickening of parts. The baths are most valuable aids to the waters in cases of weakness of the skin and convalescence from disease. Care must always be taken that excess is not drunk and dyspeptic symptoms set up by this means.

Baden-Baden (616 feet) is situated in the Grand-duchy of Baden, Germany, in a beautiful valley of the Black Forest, easily reached from Frankfort or Strasburg. It is a most popular pleasure resort, with a warm climate, the mean annual temperature being 48°, sheltered by its situation, and with abundant accommodation for visitors, of whom there are more than 4000 annually. Four of its chief springs have been united by shafts, executed under the government of the duchy. The baths are the chief means of treatment employed, but the waters, from their small amount of solid constituents, a total of 22 grains in 16 ounces, are suitable also for drinking. This is at the same time a small quantity for bath purposes, producing little more effect than the simple waters. Slight forms of gout, rheumatism, and scrofula, catarrh of stomach, and congestion of abdominal organs are benefited by Baden-Baden, while persons merely requiring change of air and relaxation without having anything specially wrong with them could not, according to Dr. Macpherson, go to a better place. Two of the springs, the Murquelle and the Fettquelle, contain appreciable quantities of lithia, and arsenic is also present, but whether they have any effect on the body is not known. The season is from 1st May to 31st October, but is at its height from the end of August to the middle of October.

Bourbonne-les-Bains (900 feet), the French Wiesbaden, is in the department of the Haute-Marne, near the station Laferté, on the Paris-Muhlhausen line. Besides the common salt and carbonic acid, as indicated in Table II., the waters contain 14 grains (to 16 ozs.) of lime salts, and a third of a grain of bromide of sodium. It is one of the stronger saline springs, suitable for such cases as have been noted in the general description of the uses of salt springs. Ague, tumours of the spleen due to malaria, and cases of torpid liver are especially the cases for Bourbonne. Two pints is the quantity of water usually drunk, in association with the baths.

Cheltenham, in the west of England, is mentioned in this group because of one spring, in which the chief ingredient is common salt, though it also contains 11¾ grains of Glauber's salt (sulphate of soda), entitling it to be placed among the bitter waters (p. 934).

Droitwich water has a very large quantity of saline ingredients, 39 grains of Glauber's salt and 38 sulphate of lime, besides the common salt mentioned in the table. It is used only for bathing in chronic rheumatic and gouty conditions, chronic skin eruptions, in lumbago and sciatica, and as a stimulant for the removal of thickenings. The waters are used diluted for the baths at a temperature between 95° and 112°.

Homburg is one of the most popular and one of the most English bathing resorts of Europe. It is a town of 8000 inhabitants, situated on an elevated ridge, and is amply provided with parks, gardens, and shady walks. Its visitors number over 11,000 annually. It is reached by railway from Frankfort-on-the-Main in half an hour. Its waters are used for bathing, for which they are heated, and for drinking. It has five springs, Elizabethenbrunnen, Luisenbrunnen, Kaiserbrunnen, Ludwigsbrunnen, and Stahlbrunnen. The first is chiefly used, and its composition in detail is as follows according to Fresenius:—

Common Salt (Chloride of Sodium),	75·7	grains	in 16
Chloride of Potassium,	2·6	,,	,,
Chloride of Calcium,	5·28	,,	,,
Chloride of Magnesium,	5·6	,,	,,
Sulphate of Lime,	0·1	,,	,,
Carbonate of Lime,	11·6	,,	,,
Carbonate of Magnesia,	0·2	,,	,,
Carbonate of Iron,	0·18	,,	,,
Carbonic Acid,	45 cubic inches.		
Temperature,	50° Fahr.		

The last-named spring—Stahl—is more strongly iron than the others; while the Ludwigsbrunnen is the weakest and pleasantest drinking water. The Elizabeth spring has an opening effect on the bowels after three glasses, and the waters are employed in congestions of abdominal organs, and are specially useful in gout, rheumatism, and dyspepsia, and to those indisposed after a winter's round of gaieties, and to the overworked

professional or business man. The more pronounced iron springs are suitable in persons debilitated by Indian heat. The bathing accommodation has of late been greatly increased; and the Kaiserbrunnen is chiefly used for the baths.

Ischia, a volcanic island at the northern corner of the Bay of Naples, has no less than 14 springs all more or less warm, the chief, Gurgitello, having a temperature of 158° F., and containing 135 grains of solids in 16 ounces, chiefly salt and carbonate of soda, charged also with carbonic acid gas. They are used in gout, rheumatism, paralysis, scrofula, skin diseases.

Ischl (1400 feet) lies in the valley of the Traun in Austria, in the Salzburg district, the nearest station being Gmunden. Its high situation and hilly surroundings confer upon it a mild equable climate, and it is specially sought in chest affections. There is excellent accommodation, a well managed hotel, and a hydropathic establishment. The waters are used for bathing, being diluted for the purpose.

Kissingen lies in the valley of the Saale, North Bavaria, six hours' railway journey from Frankfort. It is a popular resort, the visitors numbering over 13,000 annually, and there is abundant accommodation suitable for various lengths of purse. The surroundings are both interesting and beautiful. It has numerous springs, typical of the salt springs we are considering. Three of them are used for drinking, Rakoczy, Pandur, and Maxbrunnen, and others for bathing, Soolsprudel in particular. The composition of Rakoczy and Maxbrunnen in detail is as follows:—

	Ingredients in grs. per 16 ozs. Rakoczy.	Max-brunnen.
Chloride of Sodium (Common Salt),	40·75[1]	17·52[2]
Chloride of Potassium,	2·00	1·14
Chloride of Magnesium,	2·12	·51
Chloride of Lithium,	·14	·004
Sulphate of Magnesium,	4·11	·00
Sulphate of Lime,	2·72	1·06
Carbonate of Magnesium,	·11	·00
Carbonate of Iron,	·22	·00
Carbonate of Lime,	7·42	4·62
Phosphate of Lime,	·04	·03
Silica,	·09	·07
Nitrate of Sodium,	·06	·65
Bromide of Sodium,	·05	·00
Carbonic Acid Gas,	41 cub. in.	41 cub. in.

These tables exhibit the composition of the stronger and of the weaker drinking water. The former is generally taken in the morning to the extent of three to six glasses. The Pandurbrunnen resembles Rakoczy, but contains more gas. The small quantity of sulphate of lime is noticeable and advantageous, because it is not absorbed. The water of Maxbrunnen is used as an ordinary table water. The waters of Kissingen are suitable for all cases for which salt waters are employed (see p. 928). The Soolsprudel, used for bathing, contains 2 per cent of salt, and 30½ cubic inches of gas to 16 ozs., and when the water is heated the amount of gas given off is so great that giddiness and difficulty of breathing are commonly experienced, because of its inhalation.

[1] Tichborne's analysis, 1883. [2] Liebig's analysis.

Kreuznach lies in the valley of the Nahe within an hour by rail of Bingen on the Rhine. Its climate is mild in early spring and late autumn, but hot in summer. It has a high reputation for the treatment of scrofula, more patients of that kind being found here than at any other spring, as well as for affections of the womb. Its effects were believed to be due to the iodine and bromine in the water, but are, according to Braun, rather to be attributed to the drinkable character of the springs, the climatic conditions, the agreeableness of the place, and the well adapted method of treatment. "Kreuznach is a typical model as regards the mode of treatment and the internal and external application of Sool-springs." The chief spring used for drinking is the Elisenquelle, which has the following composition in grains per 16 ozs.:—

Common Salt,	72·88
Chloride of Lime,	13·39
Chloride of Magnesium,	4·07
Chloride of Potassium,	·62
Chloride of Lithium,	·61
Bromide of Magnesium,	·27
Iodide of Magnesium,	·03
Carbonate of Lime,	1·69
Carbonate of Magnesium,	·10
Carbonate of Iron,	·15
Silica,	·13

Of this water 4 ozs. are usually drunk to begin with, and the dose increased to 20 or even 30 ozs. There are several other springs, Oranienquelle, Carlshalle, Theodorshalle, and Münster-am-Stein, of which the first contains 108 grains of salt in 16 ozs., and the last only 60. In association with the drinking water, baths are systematically used, taken about an hour after drinking, at a temperature of about 90° to 92°. At first the bath lasts for a quarter of an hour, but is increased to three-quarters; and the water for the bath is strengthened by the addition of "mother-lye." To this combination of strong salt baths with the weaker drinking water Braun attributes much of the beneficial effects produced. The quantities of iodine and

bromine are too small to be credited with them. The cases for which Kreuznach has greatest repute are those of scrofulous swellings, the stimulation of the salt baths and the action of the water in promoting tissue change leading to their absorption. The water also increases the secretion from the bowels. In congestion, chronic inflammation, and thickening of the womb and other abdominal organs, in similar affections of the breasts, and in cases of painful monthly illness connected with similar conditions, they are most valuable, as well as in the other diseases indicated in the early paragraphs on salt waters.

Soden, a town of 1500 inhabitants, lies at the foot of the Taunus range, and is half an hour's journey by rail from Frankfort. It has a warm equable climate, somewhat moist, and has long been much resorted to in conditions of chronic catarrh of the lungs, consumption, and disorders of the abdominal organs. Spring, late summer, and autumn are the best times for a visit, as the heat, owing to its sheltered situation, is often oppressive in summer. About 1300 feet higher on the slope of the mountains is **Falkenstein**, which is much more bracing, though well sheltered from the north and east, and more suited for chest diseases. Soden has no less than twenty-three springs with varying quantities of common salt, but none of them with sufficient to make them very stimulating. Some of the wells contain ·2 to ·3 grain iron.

Wiesbaden, a town of 50,000 inhabitants, is the capital of Nassau, five miles north-west of Mayence, and has annually upwards of 60,000 visitors, to whom it offers all variety of accommodation. It lies in a valley exposed to the south only. Its winter climate is not severe, and in summer it is intensely hot, so that early spring or late autumn is a very suitable season. Many of the hotels have baths supplied direct from the springs, of which there are seventeen, from which the water issues warm. The water is abundant, and all is used for bathing, but only one source, Kochbrunnen, is used for drinking. The quantity of solids dissolved is so little comparatively, that the baths have the effect of little more than simple warm waters, though they are not to be used in irritable skin eruptions and eczema. They are useful for gout, rheumatism, and paralysis. Wiesbaden is " one of the most beautiful, amusing, and effective baths, rivalled but by few in its ability to satisfy all requirements, both the simplest and the most complicated, and in the excellent arrangements for the use of its waters."

The composition of the water is as follows, in grains per 16 ozs.:—

Common Salt,	52·49
Chloride of Potassium,	1·19
Chloride of Ammonium,	9·12
Chloride of Lime,	3·61
Chloride of Magnesium,	1·56
Chloride of Lithium,	·001
Sulphate of Lime,	·69
Carbonate of Lime,	3·21
Carbonate of Iron,	·04
Arseniate of Lime,	·001
Bromide of Magnesium,	·027
Carbonic Acid,	6½ cub. in.
Temperature,	156° Fahr.

It is pointed out that the drinking of such water as the above in a warm condition, and with its small amount of gas, results in the water being absorbed and passing through the body, promoting tissue change. Whereas a cold water with the same quantity of salt and more gas would stimulate stomach and bowels, producing increased activity of the bowel. All the diseases indicated on p. 928 are treated by the Wiesbaden water, and specially gout and rheumatism.

Woodhall, near Horncastle in Lincolnshire, England, has of recent years come much into repute for the treatment of rheumatism, scrofula, and uterine complaints. Its value is ascribed to the iodine and bromine it contains, and it is called the "Iodine Spa." Braun, however, believes the effects to be due to the common salt and other conditions. A recent analysis of Professor J. A. Wanklyn indicates also the presence of *free* iodine, an observation of importance, as a very minute dose of *free* iodine would yet have marked effects, and it may be that the undoubtedly beneficial influence of the water is due, to some extent, to this ingredient. The analysis in 16 ounces is as follows:—

Common Salt,	133	grains.
Chloride of Lime,	11·1	,,
Chloride of Magnesium,	9·1	,,
Carbonate of Soda,	1·0	,,
Sulphate of Soda,	·03	,,
Nitrate of Soda,	·05	,,
Free Iodine,	·02	,,
Iodine as Iodates,	·02	,,
Iodine as Iodides,	·04	,,
Bromine as Bromides,	·34	,,
Iron,	traces.	

Much has been done by the building of a well-equipped bathing-house, hotel, &c., to make the place pleasant for visitors, and in Woodhall there now exists for English invalids a rival to Kreuznach.

In America there are the **Saratoga Springs**,

of which the Empire Spring has 50½ grs. salt in 16 ozs., with 16 grs. bicarbonates of magnesia, soda, and lime, ·07 iron, traces of sodium and bromine, and 34½ cub. in. of carbonic acid gas.

Bad-Nauheim, in Hesse-Darmstadt, has of late years sprung into prominence because of the value of its waters in the treatment of chronic heart affections. The observations of the late Dr. August Schott, and the writings of his successor and brother, Dr. Theodor Schott, have made the place famous for these conditions, and the system of treatment initiated by them is called **"The Schott Treatment of Chronic Heart Affection"**.

Bad-Nauheim is a little town of barely 4000 inhabitants, nestling at the foot of a spur of the eastern slope of the Tannus Mountains. It is on the main line of the Hamburg-Hanover-Cassel-Frankfort railway, a run of about forty minutes from Frankfort. It is a nine hours' journey by express train from Hamburg; and there is through service from the Hook of Holland through Rotterdam and Cologne to Frankfort, from Flushing through Cologne, and from Calais through Brussels and Cologne, the through journey from London taking about nineteen hours. It lies at an elevation of about 450 feet above the level of the sea, and the atmosphere is dry though not exactly bracing. Homburg is distant fifteen miles across country. The Spa belongs to the Grand Duchy of Hesse-Darmstadt, and the administration has done much for the visitors who now throng to it in thousands annually. It has the usual attractions of a handsome Kur-haus, well laid-out park, and daily band performances during the season, which begins about the middle of May and lasts till October. It possesses in all six springs, two of which are used for baths, and four for drinking purposes. The baths, however, are the chief agents in treatment, much less importance being attached to drinking the waters.

The chief saline ingredients of the bathing water are common salt and chloride of calcium; the waters are exceptionally rich in carbonic acid gas; and the temperature is only a few degrees below blood-heat, between 89° and 96° Fahrenheit. One spring is named Friedrich-Wilhelm's (or No. 12), and the other "Great Sprudel" (or No. 7), and the principal details of their composition are given in the following column. It will be noticed from the analysis that No. 12 is richer in common salt, containing about 3 per cent, richer in chloride of calcium, contains less carbonic acid gas, and is of higher temperature than No. 7, but the

	Spring No. 12. (percentages.)	Spring No. 7. (percentages.)

Chloride of Calcium,.........	·232	·170
Chloride of Potassium,......	·111	·049
Chloride of Magnesium,....	·052	·044
Bicarbonate of Lime,.......	·260	·235
Free Carbonic Acid Gas,...	·197	·237
Temperature,..................	95·54° Fahr.	88·88° Fahr.

There are also small quantities of bromide, iodides, iron, arsenic, &c.

higher temperature causes the gas to come off more rapidly. Each of these springs discharges through a pipe, opening freely into the air, and carried a considerable distance vertically into the air. Round each pipe is built a reservoir, and the water escaping from the pipe, falls back into the reservoir. The reservoirs are quite open to the atmosphere; much of the carbonic acid gas, therefore, escapes, and with the escape of the gas certain salts of iron it helped to keep in solution, are precipitated out, and the water, which, as it comes from the spring, is perfectly transparent, becomes of a muddy, rusty colour. The quantity of gas dissolved in the water is so great that it drives the water out of the pipe with great force, so that it springs into the air to a distance of 40 or 50 feet, in much the same way that, were the cork removed, a soda-water bottle would drive its contents into the air. These tall, straight columns of foaming water, constantly rising into the air day and night from year's end to year's end, are a very remarkable spectacle. The reservoirs are built in the park, and in the immediate neighbourhood are the bath-houses, six in number, capable of accommodating at one time between 200 and 300 bathers.

Broadly speaking, there are three kinds of baths in use at Nauheim. I. The mildest bath is of water drawn from the reservoir, which has lost, therefore, much of its gas, which may have its temperature raised or lowered by the addition of hot water or ice, and which may be varied in strength by the addition of "mother-lye". (There are salt works in Nauheim, in which the unused water is concentrated and from which the common salt is removed, the remaining liquid is the mother lye, and this evaporated down yields bath-salt, rich in chloride of calcium, and used for making artificial baths.) II. The second kind of bath consists of water carried directly from the spring to the bath tub by a branch pipe, without previous exposure to the air. It contains the normal quantity of gas; and the water foams and bubbles as it enters the bath-tub. This bath is highly effervescent and is a peculiarity of Nauheim.

III. In the third kind of bath, the water is not turned off when the tub is full, but an overflow pipe is opened, and the patient lies in the bath while the foaming water streams through it. This is called a current-bath (strom-bad). Each of these three varieties of baths may be given with water from either of the two springs, and the springs may be mixed in the one tub, so that a great variety of bath may be given, according to the requirements of the patient.

The baths are used for a great variety of disorders—rheumatism, in its manifold forms, gout, disorders of the heart and circulation, nervous diseases and diseases of women, chronic inflammatory affections and the thickenings that accompany them. But it is for the treatment of heart affections that the waters have become famous. The saline ingredients of the waters stimulate the skin, and the carbonic acid gas forming in fine bubbles on the surface of the body, and constantly escaping from it to be replaced by fresh bubbles, maintains and accentuates this effect on the blood-vessels and nerves of the skin. A patient entering the bath, which is a few degrees below the temperature of the body, feels the water somewhat cold, and there is often a sense of oppression and constriction of the chest. This feeling lasts only a moment, and then a delightful sensation of warmth and comfort steals over him because of the action of the water on the blood-vessels of the skin. The blood is brought to the surface, so that after even 20 minutes' immersion the patient comes out of the bath warm and comfortable, the skin universally pink. The blood being thus brought to the surface, congestions of deep organs are relieved, and the absorption of inflammatory products promoted, while the action of the minute bubbles of gas on the terminal nerves of the skin acts reflexly on the nervous system, and through it on the heart, whose action is strengthened, slowed, and regulated. It is, therefore, weak and dilated conditions of the heart that are suited, *par excellence*, for this treatment, though all forms of heart disease benefit.

The "Schott Treatment" combines the uses of the baths with a system of muscular exercises with resistance, to give which there are in Nauheim men and women specially trained. The exercises consist of movements of flexion and extension of the limbs and of the trunk. For instance, the patient extends both arms straight in front of him, palms against one another. From this position he moves the arms outwards from the middle line till they are straight out from the side and in line with the shoulder. This is done very slowly, and without jerk, the patient breathing quietly and steadily all the time. The operator, standing in front of the patient, places the palms of his hands on the outside of the patient's wrists, and gently resists the movement. The operator holds the patient's arms in this position for a moment, and then the patient brings the arms forward again to the middle line, the operator resisting. The art of the operator consists in getting the patient to perform the movements quite slowly and steadily, without holding the breath, and in adjusting the resistance, which is never great, to suit the patient. To perform another of the movements the patient lets his arm hang down straight at his side, and then slowly bends the forearm on the upper arm, and straightens it again, the operator resisting meanwhile. Between each movement the patient is made to rest a few seconds. The exercises are given to the patient standing, by preference, but the patient may be seated, or even lying down. There are some half-dozen such movements for the arms, several for the legs, and others for the trunk, all of them being resisted in a particular way, and to a carefully regulated degree, by the operator. The effect of these movements, when properly adjusted to the individual case, in strengthening and slowing a weak and irritable heart can be watched by observing the pulse.

To this treatment may be added that of graduated hill exercise (terrain-kur), somewhat after the system of Oertel, of Munich. A variety of other remedial agents, common to many spas, may also be brought into operation at Nauheim, such as the whey cure, grape cure, &c.

By the use of common salt and chloride of calcium (or the Nauheim bath-salt), with acid and soda to produce effervescence, an artificial Nauheim water can be prepared anywhere, and the Schott system of treatment followed away from Nauheim. Such artificial Nauheim baths are now made use of in Bath in England and in Buxton, and may be employed by any physician anywhere.

As a result of his observations during portions of two seasons spent at Nauheim, and of the use in private practice of the artificial baths in a large number of cases, the author is convinced that no other form of treatment offers so great prospects of benefit in many disorders of the heart in which the routine treatment by rest and heart tonics has proved unsatisfactory or of merely temporary benefit.

Waters of kindred properties to those of Nauheim are to be found in Rehme-Oeynhausen, in Westphalia, and in Bourbon-Lancy in the department of Saone-et-Loire, France.

III. Bitter Waters—Aperient Waters—Sulphated Waters.

The chief ingredients of these waters are sulphate of magnesia, commonly called Epsom salts, from the once popular well at Epsom of which it was the principal constituent, and sulphate of soda or Glauber's salt, because it was first discovered and described by Glauber in 1658. The action of these salts has been sufficiently described on pp. 862 and 863. They produce, when given in sufficient doses, a profuse watery secretion from the bowels; indeed, in large doses they produce a catarrh of the bowel, and consequently their frequent use in *large* quantities is not desirable. A glance at the table will show that many of these mineral waters contain little of importance beyond the sulphates of magnesia and soda, while others contain, besides fair quantities of common salt, carbonate of soda and carbonic acid gas. The addition of these other ingredients is of considerable significance. A water which contains them will have with less of the sulphates an opening effect equal to one richer in the sulphates but without these additional constituents. Even carbonic acid gas alone, in addition to the Epsom and Glauber's salts, is a great advantage because of its tonic effect on the mucous membrane, so that a weak aerated bitter water will be of equal value with a strong non-aerated bitter water, so far as its aperient effect is concerned, and will be less likely to occasion disturbance. The same thing is true of the common salt and the carbonate of soda. Some of these waters contain iron besides the other constituents named, notably Marienbad, Carlsbad, Franzensbad, and Tarasp. One may, therefore, perceive how much more beneficial such natural and complicated waters are than a simple draught of Epsom or Glauber's salts artificially prepared. Further, Glauber's salts are milder in action than Epsom, and waters containing them rather than the latter are preferred, Carlsbad for example. Of the simple aperient waters, Püllna, Saidschütz, Sedlitz, Birmensdorf, Hunyadi Janos, and Friedrichshall are the chief; and of those which contain also carbonate of soda, as well as common salt, Carlsbad, Marienbad, Tarasp, Franzensbad, Elster, and Bertrich are the principal. Aesculap, lately introduced in bottled condition, belongs to the latter class, and so also does Mattoni's Royal Hungarian Bitter Water.

n

The chief use of these waters is in sluggish conditions of abdominal organs, in constipation, in congestion and enlargement of the liver, in piles dependent upon such states of the liver, in gall-stones, and in enlarged spleen. They are specially beneficial for persons of a too full habit of body, specially when such a condition is largely due to excess in diet and deficient exercise. The action of the waters on the bowels stimulates tissue change, and is a direct incitement to the removal of deposited fat, so that such persons lose some of their superfluous bulk, while they do not become weakened or less vigorous muscularly, under a judiciously directed course of the waters. In indigestion consequent upon sluggish circulation in the bowels, they are also useful. In some cases of gout, also, they are valuable, as may readily be understood from what has been said, and also in gravel. Some of them, specially those rich in carbonate of soda, such as Carlsbad, are made use of in diabetes with some benefit.

Aesculap is obtained from springs at Buda-Pest, in Hungary, and is bottled for use. It is an excellent aperient in doses of a wine-glassful to a tumblerful, with an equal quantity of hot water.

Carlsbad, in the Eger district of Bohemia, in a narrow valley, nearly 1200 feet above the sea-level, is a town of 12,000 inhabitants. The river Tepl runs through the valley, and the town is built on both sides. High and steep hills rise on either hand, the pine-clad slopes of which are rendered accessible by paths cut in all directions. The municipality has purchased 30,000 acres of pine-wood, which are laid out in mile upon mile of carefully-kept walks, and supplied at frequent intervals with seats for the sake of those pursuing the exercise-cure. A series of garden restaurants are set up, where visitors can breakfast or dine beneath the trees. Everything possible has been done by the municipality to attract and add to the comfort of visitors, even to the establishment of an official band, which, it is said, has few rivals in any great city. The number of visitors is 25,000 yearly. The springs are numerous, and differ little in their constituents, but vary in temperature and in the amount of dissolved gas. The chief is the Sprudel, situated in the centre of the town, over which has been erected a glass-domed building. It rises with a throbbing movement 4 or 5 feet in the air; falling back into an ornamental basin, round which stand

girls who fix the glasses of the visitors on to the end of long rods and dip them into the cauldron. The temperature of the water is 162° F., and a cloud of steam fills the building. Chief of the other springs are the Mühlbrunnen, the Schlossbrun, the Hygeiaquelle, and Theresien-

III. BITTER WATERS

(Sulphated Waters, Waters whose Chief Ingredients are Sulphate of Soda and Magnesia).

Name.	Situation.	Elevation above Sea-level in Feet.	Amounts of Chief Ingredients in Grains per 16 ozs.				CO_2* in Cubic Inches per 16 ozs.	Remarks.
			Sulphate of Magnesia (Epsom Salts).	Sulphate of Soda (Glauber's Salts).	Common Salt.	Carbonate of Soda.

Purton	Wiltshire (England)		$\underbrace{\quad\quad}_{23}$		4·2	Carbonate of potash, 3½	6	10 grs. lime sulphate.
Rohitsch (Tempelbrunnen)	Styria	730		15½	$\frac{7}{10}$	6	25	Carbonate of lime and magnesia 21, iron ½ gr.
Rubinat	Pyrenees (Spain)		5	148½	3			Dose, ½ to 1 wineglassful.
Saidschütz	Bohemia	660	84	46	2	Carbonate of magnesia, 5	0	10 grs. of indigestible sulphate of lime.
Scarborough Wells	Yorkshire (England)		17 to 28		3½		0	
Sedlitz	Bohemia		104	0	3	3	0	8 grs. lime sulphate.
Stubuya	Hungary			4			3	Hot, 111° F.
Tarasp (Great Spring)	Lower Engadine (Switz.)	4,608		16½	29½	38½	33	⅕ gr. iron. See p. 796.
Victoria-Ofner	Buda-Pest		229½	120	12	8		16 grs. lime sulphate.

* CO_2 = Carbonic acid gas.

brunnen. The composition of the Sprudel is as follows, in grains per 16 ozs.:—

Sulphate of Soda,	19·8
,, Potash,	·4
Common Salt,	8·5
Carbonate of Soda,	14·2
,, Lime,	2·0
,, Magnesia,	·3
,, Iron,	·02
,, Lithia,	·08 (Tichborne).

The waters are drunk early in the morning before breakfast, from 2 up to 8 or 10 glasses of 6 to 8 ounces each being slowly imbibed, exercise in the open air being at the same time engaged in. This usually produces a slight opening effect. About an hour after the last glass a light breakfast is taken. Dinner is at 1 o'clock. A cup of coffee is allowed in the afternoon, a light supper at 8, and 9 o'clock is the recognized hour of retiring to bed. The diet is very carefully regulated by the physicians, the meals being very plain but well cooked. Meals may all be taken in the open air, and there is no such thing as *table-d'hôte*. The Carlsbad cure

is not only a water-cure, but also a diet-cure, an air-cure, an exercise-cure, and a rest-cure. The cases suited for Carlsbad are dyspeptic cases, cases of catarrh of stomach and chronic ulcers of the stomach and catarrh of bowels, of enlarged and fatty livers, of enlarged spleen, cases in which there is a tendency to gall-stones and biliary disorders, gout, and catarrhal conditions of the kidney and urinary organs. The lean dyspeptic ill-nourished man seeks Carlsbad to get rid of his dyspepsia and to put on fat, and the fat man seeks it to stimulate his tissue change and put off some of his fatness. Improvement is also observed here in many diabetic cases. The waters are also used for baths. The season begins in May, and August and September are found very pleasant months there. The bottled water should be used before breakfast and with exercise if possible, either 2 or 3 glasses warmed to 100° Fahr., with an hour's exercise before breakfast, or a milder course of half a tumblerful warmed, sufficient to secure a gentle motion. About 3,000,000 bottles of the water and 90,000 pounds of the salt are exported annually.

Cheltenham possesses several springs, one whose chief ingredient is common salt, mentioned in Table II., another, the Pitville spring, is placed in the present list of bitter waters. There are others which contain iodine and sulphur, and one strongly iron spring which will be noted later. Braun says concerning them that their chief defect is the small quantity of carbonate of soda and carbonic acid, but that this might be remedied by the addition of a certain quantity of Bilin or Fachingen or Vals water, and they might be heated to a suitable temperature. They are much used for liver affections in dyspeptic persons.

Elster (1460 feet), on the Bohemian frontier, between Plauen and Franzensbad, has a spring, besides the one whose analysis is given in the table (Albertsbrunnen), which contains 48 grains of sulphate of soda, 12 of common salt, 7 of bicarbonate of soda, and 25 cubic inches of gas. It is called the Saltzquelle. And there are others containing very little saline ingredients at all. Moor-baths are to be had here.

Franzensbad (1569 feet) is in the neighbourhood of the town of Eger, in Bohemia; and is a town of 2000 inhabitants. It has several cold springs, Salzquelle, Wiesenquelle, Sprudel, and Franzensquelle, of which the first and the last are the most used. They resemble Carlsbad in constitution, containing, however, more gas and sulphate of soda. They also contain minute quantities of iron. It is greatly resorted to by patients suffering from anæmia (bloodlessness), pale girls of this type, and others suffering from poverty of blood resulting from some acute disease or some exhausting illness. The treatment generally adopted here is milder than at Carlsbad, and well suited to excitable and weakly persons. It is a favourite resort of patients suffering from uterine diseases, while it is suited for cases of chronic dyspepsia, catarrh of the bowels, and derangements of the genito-urinary organs. Franzensbad lies on a moor, and the materials for moor, mud, or peat baths are thus at hand in abundance, and the baths themselves are to be had in perfection. Beneath the turf is a layer, many feet in thickness, of a soft black muddy substance. This is diluted with water from one of the springs, steam is passed into it, and it is thoroughly mixed up, and then all hard masses are carefully removed. A bath-tub is filled with this material at a temperature of about 80°, into which the bather steps and remains for about 20 minutes, after which a plunge into clean water removes all black material. Such baths are employed in gout and rheumatism, in some forms of paralysis, in nervous excitement, and over-sensitiveness of the skin. It soothes restlessness, dispels fidgety sensations, and tends to produce sleep. Besides at Franzensbad they are obtained at Carlsbad, Marienbad, Teplitz, Elster, Eilsen, Driburg, Nenndorf, Meinburg, Homburg, Kissingen, and other places.

Friedrichshall is not drunk at the source, but exported only. It is an excellent water for aperient purposes, and in smaller doses for stimulating tissue change in cases similar to those for which Carlsbad is suited. From a quarter to half a tumblerful should be taken in early morning with enough hot water to make it warm, as directed for Carlsbad. In biliary derangements, torpid liver, gout, gravel, specially in the full-blooded individual, it is particularly useful.

Hunyadi Janos is one of the most useful of aperient waters, taken in the morning to the extent of a claret glassful or thereby.

Leamington has several springs besides the one whose constituents are indicated in the table. One of them contains about a grain of iron in 16 ozs., and another is a sulphur spring. Of the aperient spring the defect is the absence of carbonate of soda, which might be remedied by the addition of some other water, such as Vichy. The waters are useful for all the conditions indicated in the paragraphs devoted to the consideration of bitter waters in general, the

accommodation is good, and the winter climate comparatively mild.

Marienbad (1980 feet) is twenty-five miles from Carlsbad, an hour's journey from Eger by rail. It lies in a broad valley surrounded by pine-clad hills. The springs resemble those of Carlsbad, but are stronger, are cold, and contain more carbonic acid gas. The chief wells are the Kreuzbrunnen and the Ferdinandsbrunnen. Tichborne's analysis of the former is as follows, in grains per 16 ozs.:—

Sulphate of Soda,	32·0
Bicarbonate of Soda,	11·4
Common Salt,	10·1
Carbonate of Lithia,	·08
Carbonate of Lime,	3·0
Carbonate of Magnesia,	2·0
Carbonate of Iron,	·1

These waters, being stronger than those of Carlsbad, are taken in smaller quantities. They are usually warmed. They are bottled for home use, and may be employed in substitution for Carlsbad and for similar conditions. Two-thirds of a tumblerful and one-third hot water may be taken as a morning dose, which should be sufficient to act on the bowels. A quantity of Marienbad water diluted with almost an equal bulk of hot water makes a draught as nearly resembling Carlsbad water as possible. Marienbad is not used for diabetic patients like its rival. It has 13,000 visitors annually.

Püllna water is a popular bottled water, stronger than Friedrichshall, but with similar action, so that less is necessary, a wine-glassful made warm with hot water being taken before breakfast. Tichborne finds the water to contain evidences of contamination of surface drainage.

Tarasp has already been noted as a health resort on p. 796. It has a cold spring, which is noteworthy for the large amount of antacids it contains. Besides the 38½ grains of bicarbonate of soda noted in the table, it contains 25 grains of bicarbonate of lime and magnesia, and about 3 grains of the indigestible lime sulphate.

Scarborough wells contain too much lime salts (13¾ grs. of sulphate of lime and 6 of carbonate) to be readily absorbed, and lie heavy on the stomach.

Kingswood, in Gloucestershire, is in possession of a bitter spring—the **Cherry Rocks** bitter water; **Beulah** spa, near Norwood, contains in 16 ozs. 61 grains of Epsom and 9 of Glauber's salts, and some common salt; **Streatham** well is another English bitter spring; and there are many others now forgotten.

Kissingen, from its small amount of Epsom salts (see p. 931), might also be ranked as a bitter spa, and **Uriage** also.

IV. Simple Soda Waters (Alkaline Waters).

These are waters whose chief ingredient is bicarbonate of soda. The actions of soda and potash salts have been considered in some detail on pp. 818, 819, 844, and 845. Briefly put soda and potash salts by their direct action (1) are capable of stimulating the flow of the digestive fluid of the stomach, of the bile, and of the pancreatic juice, and thus act as stimulants to digestion and to bile excretion. (2) They directly neutralize acidity of the stomach and bowels. (3) Passing into the blood they increase its alkalinity; and it has been pointed out that a lessening of the alkaline character of the blood is at least invariably associated with rheumatism, gout, and other diseases. (4) They also diminish the acidity of the urine, lessen its irritating character, and avert or diminish the tendency to the formation of certain forms of stone. Besides, in passing through the kidney, soda and potash increase the quantity of urine. (5) Moreover soda is excreted by the lungs, increasing the secretion of the bronchial tubes, and rendering expectoration more copious and free. (6) The directly soothing effect of solutions of soda upon the skin has been referred to on p. 845.

These facts and others of a like kind offer at least some sort of explanation of the circumstances which seem to indicate the use of soda waters to be beneficial. It is quite clear that many kinds of dyspeptic disturbances will be relieved by a course of soda waters, and indigestion is almost certain to be much relieved, and irritable conditions of stomach and bowels, such conditions as are indicated by a tendency to vomiting and diarrhœa. For catarrh of stomach and bowels they are valuable remedies, though when the catarrh is chronic, more stimulating waters, such as the common salt waters, are more likely to be permanently beneficial. The waters are also employed for biliary disorders, enlarged liver, and in cases of gall-stones. In other forms of catarrh, besides that of stomach and bowels, their usefulness is admitted, specially in that of the bronchial tubes, and of kidneys and bladder. In gout and gravel they are widely used, though the more complicated waters of Carlsbad, for example, are in most cases superior. This it would appear is due to the fact that the benefit results not from the mere increased alkalinity of the blood produced, but from the increased stimulus to tissue change

and the removal of fat. This soda waters accomplish, but not so satisfactorily as the more stimulating kinds belonging to Carlsbad, Marienbad, &c. Rheumatism is also treated with the alkaline waters, and diabetes is in suitable cases, mild cases in the early stages, frequently benefited. Diseases of women are also treated, but not those attended by poverty of blood, which rather demand iron waters. Indeed it is to be observed that soda waters have a lowering tendency. The prolonged use of even small doses impairs appetite and digestion, and depresses nutrition. The soda waters which also contain appreciable amounts of common salt are more

IV. SIMPLE SODA WATERS (ALKALINE WATERS).

Name.	Situation.	Elevation in feet.	Quantity of Soda in 16 ozs.	Quantity of Carbonic Acid Gas.	Remarks.
Apollinaris	A spring near Neuenahr, in Rhenish Prussia	225	9½ grains	47 cubic inches	Cold (62°·6 F.).
Bilin	Bohemia	645	26 ,,	33 ,,	Cold. Season May to September.
Desaignes (Eau de César)	Ardèche (France)		21½ ,,	21 grains	Cold.
Fachingen	Nassau, on the Lahn	337	28 ,,	33 ,,	Cold. ·11 gr. iron.
Fellathal	Illyria		25 ,,	38 ,,	Used for indigestion.
Geilnau	Nassau		8 ,,	23 cubic inches	·3 gr. of iron, 6 of magnesia and lime. Cold.
Gerolstein	Rhenish Prussia	1,200	5·7 ,,		4 grs. carbonate of lime and 3 of magnesia.
Gettysburg	U.S.A.		4·6 ,,		15·7 grs. carbonates of magnesia and lime, and 5·3 sulphate of lime.
Giesshübel	Bohemia		10 ,,	55 ,,	3½ grs. of lime and magnesia, ·3 of iron. Cold.
Kronenquelle	See p. 938.				
Mont Dore	France (Puy-de-Dôme)	3,300	4 to 5 ,,		Warm springs, 106° to 108° F. Contain also common salt
Neuenahr	Near Bonn, Prussia	276	6 to 10·8 grs.	12 to 47 cub. in.	Hot springs, 93°·2 to 104° F. Common salt 1 to 3½ grs., carbonate of magnesia and lime 3 to 7 grs., ·7 iron.
Preblau	Carniola		21 grains	66 cubic inches	Used for indigestion.
Salzbrunn	Silesia	1,270	18 ,,	38 ,,	Bicarbonate of lime and magnesia 7 grs., iron ·002, sulphate of soda 4·7. Whey establishment, moor-baths. Cold springs.
Saint Marco	Tuscany	See p. 938.			
Soulzmatt	In the Vosges	850	9 grains	9 cubic inches	7 grs. of carbonate of magnesia and lime.
Vals	Ardèche (France)	2,475	6½ to 40 grs.	14 to 30 cub. in.	Cold. Traces of arsenic and ·04 to ·2 gr. iron.
Vichy	Central France	787	24 to 30 grs.	12½ to 14 ,,	Springs 50° to 105° F. Contain also iron and arsenic.

stimulating, and therefore more generally useful. They are mentioned in the next table. It may be observed that the most of the soda waters contain a considerable quantity of carbonic acid gas, and perhaps its slightly stimulating properties may correct some of the depressing tendencies of the soda. In some skin affections alkaline baths are of much use. It will be noticed from the table that Mont Dore, Neuenahr, and Vichy are warm springs, the others are cold. The hot springs are resorted to when it is desired to produce effects after absorption of the waters into the blood, the heat aiding that absorption; the cold springs are chosen when a stimulating effect upon stomach and bowels is specially sought. In the cold springs the quantity of carbonic acid gas is naturally much greater than in the warm waters, and this increases their stimulating properties.

To the same class belong **Chaudes Aigues,** a hot spring (143° to 178°) in Cantal, between Clermont and Toulouse, used for rheumatism and enlarged joints, **Néris,** also a hot spring (114° to 125° F.), in the department of Allier, at an elevation of 800 feet, both feeble alkaline springs, **Evian-les-Bains,** near the Lake of Geneva, a weak spring, and **Teinach,** in Würtemberg, in the Black Forest, 1225 feet above the sea.

Apollinaris is much used as a table water. It is bottled at the spring, which rises in the valley of the Ahr, in Germany, near Neuenahr. Tichborne's analysis shows the constituents in grains per 16 ozs. as follows:—

Bicarbonate of Soda,	10·62
Common Salt,	5·
Sulphate of Soda,	2·4
,, Potash,	·14
Carbonate of Magnesia,	4·5
,, Lime,	2·88

It is useful in the conditions already indicated, chiefly gout, gravel, bronchial catarrh, tendency to gall-stones; and it is a very pleasant water for ordinary use from the quantity of gas it contains. The quantity of common salt, and Glauber's salt, though too small to classify the water as salt or bitter water, is yet a valuable constituent.

Bilin is in Bohemia, two hours from Teplitz.

Constituents in 16 ounces in grains.

Bicarbonate of Soda,	26·1
Carbonate of Lime,	2·75
,, Magnesia,	1·06
Bicarbonate of Lithia,	·05
Carbonate of Iron,	·1
Sulphate of Soda,	5·13
,, Potash,	1·75
Common Salt,	2·69

This is one of the strongest soda springs in Germany. It is used in similar circumstances to Vichy.

Mont Dore (3300 feet) is three or four hours' driving distance from the railway-station of Clermont-Ferrand, in the department of the Puy-de-Dôme, lying in the Dordogne valley of the Auvergne Mountains. It has six warm springs and one cold. Here there is an excellent bathing establishment, and all varieties of baths are much used in treatment. Inhalations are also given. The place is chiefly resorted to for lung affections, chronic bronchitis, and threatened phthisis, its elevation adding to its suitability for such cases. The season extends from the middle of June to the middle of September, but July is the best month. For cases of rheumatism it is also employed.

Neuenahr is situated in the valley of the Ahr not far from the Rhine, and between Bonn and Coblentz. It has four warm springs, none of them rich in solid ingredients, but all rich in carbonic acid gas, and one cold spring, rich in gas. The scenery in the neighbourhood is picturesque, the town is provided with public gardens and excellent bathing establishments, and the place has become much frequented. The waters are used for gout, rheumatism, scrofula, gravel, and catarrh, alike of digestive organs, bronchial tubes, and bladder. The small quantity of soda, 10·8 grains in the richest spring and only 6 in two of them, renders it questionable whether the benefit is greater than would be achieved by the use of indifferent waters.

Salzbrunn (1270 feet) is situated in Silesia, in a wooded valley, 43 miles distant by railway from Breslau. It has two springs used for bathing and two for drinking. They are cold, and while not very rich in saline ingredients, contain a good supply of gas. It has every advantage in the way of excellent establishments under medical supervision. Its high situation renders it specially serviceable in lung affections. A whey establishment is found, and mud-baths are to be had. The season is from May to October. Since 1880 another water has been introduced from Salzbrunn—Obersalzbrunn—the **Kronenquelle**, or Crown Spring water. The spring rises in the "Prussian Crown" hotel. Its composition is given as follows in grains per 16 ozs.:

Bicarbonate of Soda,	6·1
Bicarbonate of Lithia,	·08
Bicarbonate of Lime,	4·98
Bicarbonate of Magnesia,	2·83
Bicarbonate of Strontia,	·02
Carbonate of Iron,	·06
Common Salt,	·41
Sulphate of Soda,	1·26
Sulphate of Potash,	·28

The quantity of carbonic acid gas is 13½ per cent.

The water is specially recommended in cases of gravel and gout. It is imported in bottles, and may be used as Vichy or Vals.

Saint Marco water has been recently introduced for gravel, gout, rheumatism, and liver and kidney affections. It is sold in bottles, and is derived from a spring on the Marucheto estate in Tuscany. Its chief feature is the considerable quantity of lithia present. Each 16 ozs. contain—

9·116	grains	**Bicarbonate of Soda,**
11·395	,,	Bicarbonate of Magnesia,
1·869	,,	Carbonate of Lithia,
·701	,,	Bicarbonate of Lime,
4·663	,,	Common Salt,
4·567	,,	Sulphate of Soda,
2·155	,,	Sulphate of Potash.

Lozenges are prepared from salts of the spring.

Vals is situated in the Ardèche. The railway-station is Aubenas, from which it is 4 miles distant. It has several springs—Magdeleine, Précieuse, Désirée, Rigolette, and St. Jean. The last is the weakest and the first the strongest, Magdeleine containing 51 grains of bicarbonate of soda in 16 ozs. according to one analysis, and St. Jean only 10·3 according to the same chemist. The former and the spring Rigolette contain also nearly ·2 grain iron, and are used in the weaker classes of cases. At Vals there is also a spring—Dominique—which contains ·005 grain in 16 ozs., and is used in debilitated conditions and in intermittent fevers, and malarial affections of the spleen. Vals waters are, like those of Vichy, bottled under government supervision.

Vichy (787 feet) is situated on the Allier river, in an open valley at the foot of the Auvergne Mountains. It is south of Paris, a distance of about 7 hours' journey by fast train, and on a branch of the Paris and Lyons railway, and the springs, which are nine in number, are the property of the government, and are managed by the Compagnie Fermière de Vichy under the supervision of the government. The waters are drunk on the spot, are used for baths, and are bottled for export; while the Vichy salts, obtained by the evaporation of the waters, are manufactured into lozenges. The mineral establishments are conducted on a magnificent scale, the hotel accommodation is of great variety, and because of these and other circumstances Vichy is the most crowded spa in Europe. The season is from the middle of May to the middle of September, but July is unbearably hot. The daily flow of water from the springs is 113 gallons. In certain parts of the season the quantity required for baths, &c., exceeds this amount. So large vaulted cisterns, 12 feet deep, have been constructed in which the water is stored when less is being used, and from these vaults it is thought a water of more constant composition is obtained. The chief springs are Grande-Grille, Hôpital, Hauterive, Mesdames, Celestins, Parc, Grand-Puits Carré, and Petit-Puits. The last two are chiefly used for baths. The composition of five of these springs is given by Tichborne from a recent analysis as follows, in grains per 16 ozs.:—

	Grande-Grille.	Mesdames.	Hôpital.	Parc.	Hauterive.
Bicarbonate of Soda,	29·48	24·03	31·42	29·8	30·
Bicarbonate of Potash,	2·16	1·12	·42	1·83	1·20
Carbonate of Magnesia,	1·86	2·63	1·23	1·3	3·20
Carbonate of Strontium,	1·9	·02	·02	·04	·02
Carbonate of Lime,	2·66	3·60	3·60	3·82	2·76
Carbonate of Iron,	·03	·20	·02	·02	·1
Sulphate of Soda,	1·81	1·63	1·83	2·01	1·86
Phosphate of Soda,	·8	·03	·3	·93	·3
Arsenic,	·009	·038	·007	·008	·008
Common Salt,	3·28	2·114	3·23	2·857	3·415
Temperature in degrees F.,	105°·8	62°·6	89°	71°·6	59°

The quantity of carbonic acid is from 12 to 13 cubic inches.

The springs of Vichy are the typical alkaline springs, the carbonate of soda being the chief ingredient, the other constituents existing in such small quantity that it is impossible to estimate their exact influence on the action of the waters, though they probably modify the effects on the body. The remarks that have been made on alkaline waters in general fully apply, therefore, to the Vichy waters. The chief complaints because of which recourse is had to Vichy are urinary affections, catarrh of the bladder, stone and gravel; many gouty and rheumatic patients resort to Vichy, the latter class specially for the baths. Catarrh of stomach and bowels, enlargement of the liver and spleen, various disorders of digestion, heart-burn, painful digestion, gall-stones, and biliary colic are also suitably treated by a course of Vichy waters. Vichy water is the chief mineral water for use in diabetes, and in the milder forms of the disease is said to produce marked improvement. Vichy and Carlsbad are the two chief waters for this purpose. The Vichy waters and baths are also much used in uterine affections. Corpulence is also effectively treated by these waters. It is to be noted that the Mesdames spring contains more iron than any of the others, and it is, accordingly, employed for the weaker class of patients. Hauterive, and a spring resembling it, Celestins, is said to be less suited than Grande-Grille and Hôpital for irritable and nervous patients.

The bottled waters are taken before meals, from ½ to 2 pints being consumed daily, and they are used to stimulate digestion and remove acidity. The lozenges, "pastilles digestives," are similarly used, four, five, or six being taken before meals, while the dry Vichy salts are used for baths. Each packet contains ½ lb., the quantity needful for one bath.

The season at the springs begins on the 15th May and closes at the end of September; but the thermal establishment is open all the year, and October and November, and from February onwards, are not unfavourable times.

Besides the springs named, there are others, notably the spring Larbaud, and the spring Lardy, both provided with thermal establishments. The waters of both of these springs contain also a small proportion of iron, in the form of carbonate; the former containing ·2 grain in 16 ozs. and the latter ·16.

V. Soda Waters with Common Salt (Muriated Soda Waters).

It is not necessary to make any very detailed remarks upon this class of waters. The carbonate of soda is still the chief ingredient, and the common salt is believed to add to its effect and correct any tendency to bad results. It has been pointed out that soda tends to have a depressing effect on nutrition by hastening the destructive change of substance. This is believed to be partly, at least, the means by which fat is lessened and emaciation produced. The presence of any quantity of common salt, in addition, promotes the constructive portion of the tissue change. Thus Braun says, "Chloride of sodium (common salt) is an important corrective as regards both the local and the general effect of the carbonate of soda, . . . and, for most of the conditions requiring soda waters, a considerable amount of common salt in them is all the more to be recommended, the greater the amount of carbonate of soda which they contain. To this may be traced, in great part, the pre-eminence which, after years of experience, has been obtained by the waters of Ems and Selters, and even by Roisdorf, above pure soda waters, and the rapid prosperity of Gleichenberg, and especially of Luhatschowitz. It would be well worth the trouble in cases in which the strong soda waters of Vichy, Vals, Bilin, and Fachingen have failed in their effect, or have manifested bad incidental results, to render them muriatic alkaline waters by the corresponding addition of chloride of sodium." Whenever in addition to the correction of acidity of the stomach and bowels, &c., a stimulating effect upon digestion and tissue change is desired these soda waters with salt are to be preferred.

V. SODA WATERS WITH CARBONIC ACID GAS, AND CONTAINING ALSO COMMON SALT.

(Muriated Alkaline Waters, Muriatic Soda Waters.)

Name.	Situation.	Elevation above Sea in feet.	Amount of chief Constituents in 16 ozs.			Remarks.
			Soda in grains.	Common Salt in grains.	CO_2* in cubic in.	
Ems	Nassau	291	15	7	19	Warm springs.
Birresborn	Rhenish Prussia	1,100	20	7	17 grs.	Contains 9½ grs. bicarbonate magnesia and lime.
Gleichenberg	Styria	872	27	14	35	Cold. Carbonate of lime and magnesia, of each 4 grs. Several springs, one—the Klausner—contains ·66 gr. iron.
Kainzenbad	Upper Bavaria	2,400	4	—	—	Moor-baths. Excellent climate, good bath arrangements, climatic health resort. Sulphur and iron springs here also.
La Bourboule (Choussy).	Auvergne (France).	2,600	10	22	abundant	Warm springs. Contains also arsenious acid, ·08 gr. (See p. 951.)
Luhatschowitz	Moravia	1,600	33 to 61	23 to 33	14 to 50	Four different springs. Cold. Contains bromide of sodium ·255 gr., iodide of sodium ·132, and carbonate of iron ·111. Whey establishment.
Roisdorf†	Rhenish Prussia	1,000	9	3 to 14	19	Contains iron ·2 gr.
Royat	Puy-de-Dôme (Fr.).	1,380	5 to 9½	10 to 12	—	Warm springs, 66° to 96° F.
Selters	Nassau	800	10	17	30	
Vic-sur-Cère	Cantal	—	15	11	—	7 to 8 of sulphate of soda. Minute quantities of iron and arsenic. Used in liver and kidney affections.

* CO_2=Carbonic acid gas. † Exported only.

Other waters belonging to the same class are **Tönnisstein**, near Brohl on the Rhine, which has a cold spring, the water of which is exported, and **Szezawnica**, in Galicia, 1050 feet above sea-level, whose waters are cold, and richer in soda and salt and carbonic acid gas than Ems or Gleichenberg.

Ems is situated on the Lahn, in a narrow valley of Nassau, surrounded by wooded and vine-clad rocky heights. It is a few miles east of Coblentz and about 25 north of Schwalbach. The spring is at a little distance from the town, which now numbers nearly 7000 inhabitants, increased by 8000 visitors during the season. The climate is mild but moist, and in summer relaxing, specially so in July and August, so that May and June, September and October, are the best months. It is unsuitable for consumptives. Ems is easily reached from England, is provided with excellent hotels, and is quite a desirable place for

English needing its treatment. "There are few bathing resorts," says Braun, "where a sick person may find in intercourse with nature and man, and in the enjoyment of a brilliant and yet somewhat unpretending spa-life, such rich opportunity both for coming out of himself and for self-reflection; in both respects Ems is the pearl of Germany." The two chief springs are Krähnchen and Kesselbrunnen. The following table from Fresenius shows their composition in grains per 16 ozs.:—

	Krähnchen.	Kesselbrunnen.
Bicarbonate of Soda,	14·8	15·19
Bicarbonate of Magnesia,	1·505	1·436
Bicarbonate of Lime,	1·724	1·812
Bicarbonate of Iron,	·016	·027
Common Salt,	7·084	7·77
Sulphate of Soda,	·137	·006
Sulphate of Potash,	·328	·393
Carbonic Acid Gas,	83 cub. in.	67 cub. in.
Temperature,	84°·2 F.	114°·8 F.

Ems waters are specially employed for chronic catarrh of the air-passages, specially in gouty persons, as well as for disorders of digestion, sluggish liver, &c. A spring—Bubenquelle—used for bathing purposes, and particularly in the form of an ascending douche, used to be famous for disorders of the womb and sterility consequent upon them.

Gleichenberg (872 feet) "is situated in a pleasant hilly country," 7 miles from Gratz in Styria. Its waters are somewhat richer in carbonate of soda and in common salt than those of Ems, and "in a climatic point of view it deserves the preference." Its climate is mild, and the district is attractive.

Luhatschowitz, 2½ miles from the Hradisch station on the North-Austrian Railway, has springs rich in alkaline constituents, which serve all the purposes for which soda springs with salt are suitable. The climate is mild but moist, as it lies in a valley, though 1600 feet above sea-level.

Royat (1380 feet) is a little over a mile from Clermont-Ferrand, in a beautiful valley of the Auvergne Mountains. There are four springs, Eugénie, St. Mart, Cæsar, and St. Victor, of which the constituents in grains per 16 ozs. are as follows:—

	Eugénie.	St. Mart.
Bicarbonate of Soda,	9·443	5·12
Bicarbonate of Potash,	3·045	1·09
Carbonate of Lime,	7·000	3·71
Carbonate of Magnesia,	4·7	2·37
Carbonate of Iron,	·28	·14
Sulphate of Soda,	1·295	1·05
Phosphate of Soda,	·126	trace
Common Salt,	12·096	9·98
Chloride of Lithia,	·245	·22

Traces of arseniate, iodide, and bromide of soda.

The Victor spring is stronger than St. Mart, and in particular in iron, containing ·39 grain. The waters are largely used for gout and rheumatism, catarrhal affections of stomach and bowels, kidneys and bladder; and the St. Victor spring is specially fitted for delicate persons, sufferers from debility, bloodlessness, and for delicate women suffering from complaints connected with the generative organs. Royat is a good substitute for Ems, and its climate is preferable, especially in July and August. There is a thermal establishment fitted up with all modern bathing appliances.

Selters water is used only in the bottled form, and is not drunk at the springs. The town of Selters is a short distance from Schwalbach (p. 950). Tichborne's analysis—the most recent—is as follows (grains per 16 ozs.):—

Bicarbonate of Soda,	4·7
Carbonate of Lime,	2·2
Carbonate of Magnesia,	2·15
Chloride of Magnesia,	1·50
Carbonate of Iron,	·15
Common Salt,	16·24
Chloride of Potash,	·24
Sulphate of Soda,	·21
Phosphate of Soda,	·31
Carbonic Acid,	30 cub. in.

VI. Sulphur Waters.

Sulphur waters are those which contain sulphuretted hydrogen gas in solution. This gas is a compound of sulphur and hydrogen, and its chemical symbol is H_2S. It is a gas of a very fœtid smell, familiar enough to everyone as produced in the decomposition of albuminous materials. It is the development of this gas which causes the particularly offensive smell of rotten eggs. Sulphur waters either contain this gas in solution, or they contain substances which by chemical changes yield the gas. Such substances are chiefly sulphides, sulphides of soda, lime, potash, and magnesia, and to some extent also sulphates.

Sulphur waters are used both for bathing and for drinking purposes. Whatever may be the effects of sulphur waters when taken internally for any time, it is now generally believed that baths of sulphur water cannot produce any effect, which cannot equally well be produced by ordinary warm baths. It is pointed out that the quantity of sulphuretted hydrogen in most of the waters is so small that it can hardly have any specially stimulating effect upon the skin, and that in the ordinary bath no chemical change occurs to produce more of the gas, a change which, however, may occur in the stomach when

the water is drunk. It is also pointed out that no indications of sulphuretted hydrogen having passed into the blood through the skin are ever produced. Braun, therefore, concludes that the sulphur baths are probably nothing better than ordinary water baths. It is also to be remembered that the most famous sulphur baths are those of the Pyrénées, where all the advantages of mountain air and elevated situation combine with the courses of baths and waters.

It is, however, admitted that valuable effects are produced when sulphur waters are taken internally, and it is to the sulphuretted hydrogen actually present in the water when it is drunk, or produced from sulphides after drinking, that much of the beneficial effect is due. The sulphuretted hydrogen passes from the stomach into the blood, proceeding to the liver, and combines with blood corpuscles in course of breaking down, leading to their speedier removal from the body. During a course of such waters the motions become dark and finally black in colour, due it is said to the expulsion of this waste from the liver. Evidence of such a quickening of destructive change in the blood is found in the production of some amount of poverty of blood, requiring the use of a generous meat diet, and sometimes a course of iron waters subsequent to the sulphur.

On this account sulphur waters are employed in cases of torpid and enlarged liver, in cases of piles, in cases of catarrh of the air-passages, associated with such conditions of the liver and bowels, in early cases of consumption, and in various other affections of the lungs. How far the benefit experienced by sufferers from such lung affections is due to the sulphur water and how far to the mountain air of the resort is an interesting question. Various skin diseases, old ulcers, gunshot wounds, gout, rheumatism, and syphilis are also treated by the baths; and cases of chronic metallic poisoning, especially lead poisoning, are benefited by courses of the waters. The liver is the chief organ where metallic poisons are deposited, and it may be that the action of the sulphur on the blood flowing to the liver facilitates the removal of the deposits. The drinking of sulphur water is attended rather by constipation than by relaxation of the bowels, and they do not improve the appetite as do most other mineral waters, though they do not impair it.

At many of the sulphur water resorts the remedy is employed not only in baths and courses of the drinking waters, but by inhalation of the gas escaping from the water. This is thought to be serviceable in affections of the air-passages and in consumptive disease of the lungs. The air inhaled contains of course only a very small percentage of the sulphuretted hydrogen, for the inhalation of any quantity of the gas produces symptoms of poisoning, giddiness, faintness, headache, trembling, and in fatal quantity convulsions and delirium. Even a small percentage of the gas in the air will produce feelings of general discomfort and headache.

It has been already pointed out (p. 827) that some of these waters are employed to yield up their sulphuretted hydrogen for injection into the bowel as a treatment for consumption.

The table on the following page contains the names and chief facts concerning most of the sulphur waters in use; and only of a few of these will any further remarks be made.

Aix-les-Bains, in French Savoy, is one of the most fashionable and frequented of spas, chiefly on account of the baths, for which the arrangements are on a most complete scale, every variety of bath being provided, and inhalation chambers also. The town is in a beautiful neighbourhood, at an elevation of 850 feet, and very near some of the pleasantest scenery in the Alps. Living is moderate, there is agreeable society, and it will be found on the whole one of the most pleasant of resorts. It is a station on the railway from Paris to Mont Cenis, an eleven hours' journey from Paris, and a three hours' journey from Geneva. The springs are hot; the waters are abundant, yielding a million gallons a day; and they are chiefly used for baths in rheumatism, gout, sciatica, and nervous affections. Though the waters are used for drinking, they are too weak to yield the full effects of sulphur waters, but near to Aix are the sulphur springs of **Marliox**, which are cold and can be used for drinking in combination with the hot baths of Aix. Near to Chambéry, nine miles from Aix, is the spring of **Challes**, a strong sulphur water, containing also iodides and bromides, which is brought to Aix-les-Bains to compensate for its weak waters. The season begins early in May and lasts till October, though during the latter part of July and the early part of August the heat is rather great for comfort.

Aix-la-Chapelle or Aachen, the *Aquis Granum* of the Romans, between Brussels and Cologne, is the chief sulphur bathing resort of Germany. It is a town of over 85,000 inhabitants. The baths are exceedingly complete, though the surroundings are not nearly so engaging as those of Aix-les-Bains. The considerable quantity of

White Sulphur Springs	West Virginia, U.S.	2,000	62°	·02			6½	½		1 cub. in. CO_2.

Abano and Battaglia, on the line from Padua to Bologna, are hot springs from the Enganean range, stronger in salt than but otherwise similar to Aix-la-Chapelle.

Lavey, in the Rhone valley, near the station St. Maurice, 1420 feet high, has hot sulphur springs with common salt and sulphate of soda.

[1] CO_2 means carbonic acid gas.

common salt in the water is noted in the table, and doubtless much of the efficacy of the water is due to it. The waters are used for drinking as well as for baths. Drawn from the spring it is very hot, and visitors sip it as they promenade up and down. They usually begin with 6 or 8 ounces, and gradually increase to a pint or a pint and a half. The baths are usually prolonged from a half to three-quarters of an hour. Rheumatism, gout, nervous cases, syphilis, stiff joints, skin diseases, diseases of liver and abdominal derangements generally, and cases of metallic poisoning are treated here. The season is from June to the end of September, but the baths are open all winter. The water is exported also. **Burtscheid** is situated so near Aix-la-Chapelle that it may be called a suburb, but its springs though hotter are less strong in sulphur.

Amélie-les-Bains (680 feet), in the Pyrénées, 24 miles south of Perpignan, is provided with all sorts of bathing arrangements, which are specially employed in rheumatic cases, and with arrangements for inhalation, used in cases of consumption, for which its mild climate is specially suited. It is also suitable for a winter residence.

Allevard-les-Bains (1473 feet), in south-eastern France, has of late come into repute for the treatment of chest affections, bronchitis, asthma, &c., and also for skin affections and rheumatism. It is two hours' journey from Grenoble, and six from Lyons or Geneva. The nearest station is Goncelin.

Barèges (4200 feet), 12 miles from the railway-station of Pierrefitte, is one of the highest and most famous springs of the Pyrénées. It is resorted to for paralysis, rheumatism, old wounds, skin diseases, and bone diseases. The accommodation, however, is poor, and the surroundings dismal. A peculiar organic matter of a gelatinous nature found on the surface of the water is called **baregine**, from the name of the town. The season is July and August.

Bagnères de Luchon (2000 feet), in the valley of Luchon, 5 hours' journey by rail from Toulouse, is surrounded by the splendid scenery of the Pyrénées. Although this water contains very little sulphuretted hydrogen, yet as soon as it is drawn into the bath it becomes milky, as if from the deposit of sulphur, and the gas is developed and escapes into the air, which immediately above the bath contains as much as 1 per cent of the gas. It has been supposed that silica contained in the water takes part in this change.

Cauterets (3250 feet), in the Hautes-Pyrénées, 6 miles from Pierrefitte railway-station, is much frequented by persons suffering from chest affections. Chronic rheumatism and skin diseases, uterine affections and early stages of consumption are also treated. The situation is high, and much of the benefit may be due thereto, though horses "from the studs of Tarbes and Pau, which are afflicted with chronic bronchial and stomach catarrh, diarrhœa, emaciation and spermatorrhœa, are sent to the springs at Cauterets, and are often cured there in a week" (Braun). The climate is variable; and the best months are July, August, and September.

Eaux Bonnes is situated in the Pyrénées at an elevation of 2434 feet, in a narrow sheltered ravine, at the foot of the Pic du Gers, and is reached from Pau, from which it is distant 20 miles. The climate is subject to sudden changes of temperature, but the situation and scenery are very attractive. It is said to produce excellent results in clergyman's sore throat and lung affections, specially of the tubercular kind, which may be due to the elevated situation. The water is taken in very small quantity to begin with, a table-spoonful or so, and is cautiously increased to 4 or 5 glasses daily.

Eaux Chaudes (2215 feet), also in the Pyrénées, is reached by diligence from Pau, and is situated in a narrow and picturesque but gloomy gorge, and subject to rather sudden changes of temperature. The waters are chiefly used for baths in cases of chronic rheumatism, muscular rheumatism, and chlorosis and neuralgias. It is 4 miles distant from Eaux Bonnes. The season is from 1st June to 1st October.

Harrogate is in Yorkshire, 30 miles west of York, partly situated on high ground (600 feet) and partly in the valley. The air is pure and bracing but moist, and the soil is sandy and readily dries after rain. It contains not only sulphur wells which are among the strongest known, but also iron springs. There are considerable social attractions, and during the season, June to October, the climate is pleasant. The waters are taken between 7 and 8 a.m., and the dose is from one to three tumblerfuls, a short walk being taken between each glass, the third being followed by a longer walk back for breakfast. The waters open the bowels, acting upon the liver also, and removing constipation. They are thus useful also for sluggish liver, abdominal congestion and piles, especially when resulting from rich living. They also promote change of tissue and are used as a

remedy for corpulence and for the removal of thickenings of glands and gouty and rheumatic swellings. They are useful for full-blooded persons with a tendency to apoplexy, also in cases of enlargement of the womb; and it is a favourite resort for overworked business men. A course of eight days to three weeks is usually taken in the quantities already named, when the opening action is chiefly sought, and when the waters are taken to promote tissue change from 2 to 8 ounces is the quantity taken cold three or four times a day. If the waters lie heavy on the stomach they are taken warm. Chronic rheumatism, gout, and syphilis are also treated. Cases of threatened consumption, and disorders of the monthly illness in young persons are treated with the sulphur baths, and the iron waters internally. Much of the effect of the sulphur waters is believed to be due to the large quantity of common salt contained in the waters.

Moffat in Dumfriesshire, Scotland, is an excellent health resort in summer and up to the middle of September. Its climate is good, and much picturesque scenery is within easy driving distance. The well is fully a mile from the town; the waters are very mild but generally suitable for cases similar to those described for Harrogate. A hydropathic establishment is within a mile of the railway-station.

Saint Sauveur (2360 feet) is a fashionable "ladies' bath," being much used by women for nervous complaints and affections of the generative organs. It is approached from Lourdes, is 4 miles from Barèges and is close to some of the finest scenery of the Pyrénées. The season commences in May and ends in October.

Strathpeffer, amid wild and picturesque scenery at the foot of Ben Wyvis in Ross-shire, Scotland, is becoming more frequented since the building of a suitable establishment near the wells. There are two springs, the upper being the strongest sulphur spring in Britain. The water acts strongly on the kidneys, but is constipating owing to the large quantity of lime salts. Three tumblers are usually taken before breakfast and as many more in the afternoon. Chronic cases of sciatica, lumbago, and rheumatism find relief; and the water has a strong effect on the skin, shown by the cuticle coming off in scurf.

Lisdunvarna, in Ireland, about 20 miles from Ennis, possesses a sulphur spring, containing ½ a cubic inch of sulphuretted hydrogen in 16 ozs., and several iron springs, but the place has no suitable arrangements for visitors.

VII. Earthy Mineral Waters (Lime Waters).

The earthy mineral waters are those in which lime is a prominent constituent. It occurs in the form of carbonate and sulphate. Of the two, the carbonate is the salt to be desired, and the sulphate of lime in any quantity equal to 10 grains or upwards is undesirable, because it lies heavily upon the stomach and lessens the absorption of the water into the blood. Carbonate of magnesia is another salt which occurs specially in earthy mineral waters, and is more readily absorbed than the lime salts.

It was believed at one time that these waters had a special value in diseases of bone, in rickets, in the disease called osteomalachia, because they supplied lime to the system, a deficiency of which was supposed to be at the root of the disorder. It is quite clear, however, that abundance of lime salts is supplied in the food eaten and in water, and that the disease is not due to deficiency of the phosphate of lime, but to some digestive derangement or to some disorder of the tissues which prevents the lime salts obtained from the food being made proper use of in the body. Consequently such bone diseases are treated by appropriate food, tonic treatment of various kinds, and change of air. Lime waters have, however, other uses. They correct acidity of the stomach and bowels, and they appear to be useful in gravel and in kidney and bladder affections. They are somewhat constipating, and, therefore, useful in diarrhœa and irritable conditions of the bowels. They have a reputation in scrofula, gland diseases, and tubercular disease, but there is no satisfactory reason for such repute. Earthy waters are used as baths, but the lime salts they contain are of no effect, and do not modify the action of the simple water.

Many of the waters already named contain considerable proportions of lime salts; thus of the waters named in the last table the water of Baden in Austria contains 5 grains of sulphate in 16 ounces, Baden in Switzerland 10 grains, Eilsen 17 grains, Grosswardein 2 to 3 grains, Nenndorf 5 to 8 grains, Schinznach 6 grains, Pystjan 4 grains, Töplitz 1 to 3 grains, while carbonate of lime is contained in Eilsen water, that of Aix-la-Chapelle, Baden near Vienna, Baden in Switzerland, Grosswardein, Nenndorf, Harkany, and Weilbach. In Table II., Baden-Baden, Canstatt, Cronthal, Dürkheim, Homburg, Mergentheim, Mondorf, Nauheim, Pyrmont, Schmalkalden, and Wildegg have been

mentioned as containing various quantities of these lime salts. In Table III. the presence of sulphate of lime in several of the bitter waters is noted in some quantity, and in Tables IV. and V. the presence of carbonate of lime in the soda waters. In all these waters the lime salts have been unimportant constituents in comparison with the other ingredients, worthy of note only when present in such quantity as to make the water difficult of digestion. In the present waters, however, the absence of other ingredients in quantity makes the lime salts the chief feature of the water. For this reason it must be understood the table does not include all waters containing lime salts in any proportion, in which case it would be of great length, but only those in which they rank as the chief ingredients from the absence of others.

VII. EARTHY MINERAL WATERS (WATERS CONTAINING LIME).

Name.	Situation.	Altitude in feet.	Chief Constituents in grains per 16 ozs.					CO_2* in Cubic Inches.	Remarks.
			Lime as Carbonate.	Lime as Sulphate.	Other Carbonates, Soda, Magnesia, &c.	Other Sulphates, Potash, Soda.	Common Salt.		
Alet	Aude (France)	650	1·89	·2	·8	—	·3		Used in stomach and bowel affections.
Bethesda	Wisconsin, U.S.A.	—	2·04	—	1·6	·1	·139		Prescribed in kidney and bladder diseases and in diabetes.
Buffalo Lithia	Virginia, U.S.A.	500	1½ to 4	2 to 3	·15 to 3	1	$\frac{1}{10}$ to ½	1 to 6	½ cubic in. sulphuretted hydrogen.
Chateldon	Puy-de-Dôme, France		3·61	·35	4½	—	·2	15 grains	·245 iron.
Condillac	Vaucluse (Fr.)	Imported as a table water.							
Contrexéville	Vosges (Fr.)	1,000	2¾	8	⅕	1¾	—	½ grain	
Couzan	France								
Cransac	near Aubin in Auvergne	Besides sulphates of lime and magnesia contains 13 grains sulphate of alumina in 16 ozs. Used in enlargements of liver and spleen, and intermittent fever.							
Inselbad	Westphalia		2	0	—	0	6	trace	·02 iron, 2·78 cub. in. of nitrogen; used for inhalation in cases of consumption.
Johannisbrunnen	From spring near Niederselters in Nassau.		3½		2¾	½	15	abundant	A sparkling table water.
Leukerbad (Lorenzspring)	Switzerland	4,670	0	10½	—	nearly 3	(see p. 927).		Warm, contains ·079 iron.
Lippspringe	Westphalia	441	5	2	—	7¾	nearly 2	5	·1 iron.
Lucca	See Table I.								
Poland Spring	Maine, U.S.A.	800	·135	Practically an indifferent water. Used specially in kidney disease and diabetes. Excellent accommodation.					
Pougues	Loire (France)	780	9·28	1·33	11·2	1·89	2·45 chloride of magnesia	little	·14 iron.
St. Galmier (Source Nouvelle)	Loire (Fr.)	1,350	with magnesia 3·4	with soda 1·2	3	·55	1·5	abundant	·06 iron, an excellent table water.
Sulis	See Bath, p. 925								
Taunus	Table water from spring near Frankfort-on-the-Main	390	9½	½	1·3	—	18	20 grains	
Weissenburg	near Thun	2,758	0	17		5		¾	
Wildungen	Waldeck	740	5 to 9	0	5 to 16	⅓ to ½	8	33	

* Carbonic acid gas.

Bethesda and Buffalo Lithia Springs are both in the United States of America. The former is at Waukesha, in Wisconsin, and the latter in Virginia. I have no authoritative statement as to their physiological action and curative effects. Bethesda water is, however, lauded in Bright's disease of the kidney and in various kidney and bladder affections, and very specially in diabetes. The Buffalo water is deemed valuable on account of the carbonate of lithia it contains to the extent of from ·148 to ·225 of a grain in 16 ounces. It is recommended in gout, rheumatism, gravel, disease of the kidney, specially chronic Bright's disease, and bladder, and in stomach and bowel disorders. It is said to contain sulphuretted hydrogen. Both are to be had in bottles.

Contrexéville (1000 feet) is situated in a narrow valley of the Vosges Mountains, over a thousand feet above sea-level. It is subject to sudden changes of temperature both morning and evening, a fact visitors should remember. It has a special reputation in the treatment of gravel and stone, as well as diseases of the

kidney, catarrhal affections of the bladder and prostate gland, in gout and liver disorders, in incontinence of urine in children, and in diabetes. Patients begin with two or three glasses in the morning before breakfast and gradually increase the quantity to 12, 15, or upwards. There is a well-equipped bathing establishment, and abundance of hotels. There are several springs, the Pavilion being the chief. Its waters contain a small quantity of iron, ·05 grain in 16 ounces, and a trace of arsenic. The water is largely exported. From half to one bottle is taken daily with food as a table water, or in milk or wine or spirit. The season is from 20th May to 15th September.

Lippspringe and Inselbad, near Paderborn in Westphalia, are specially resorted to in consumption and other affections of the chest. One to three glasses of the water are drunk in the morning and one or two in the afternoon. Baths are also employed. The repute of the place is to some extent due to the nitrogen gas contained in the waters, which is given off in chambers in which patients inhale it.

Pougues (780 feet) at one time enjoyed great popularity for dyspepsia and bladder irritability and catarrh. It lies in the valley of the Loire, not far from Nevers, in a pleasant country, and much has lately been done to restore its celebrity. Its waters are imported.

Weissenburg lies in a narrow gorge off the Simmenthal in Switzerland, 3 miles from Thun, surrounded by mountains and pine-trees. "The air is calm, mild, and moist, but the weather variable." It has a great reputation in cases of chronic bronchial catarrh and consumption, believed to be due rather to its elevation (2758 feet), its sheltered situation, calm air, and atmosphere of pine-wood, than to its spring.

Wildungen lies in a valley of Waldeck, 300 feet above sea-level. It is three hours' journey from the Wabern station on the Main and Weser railway. Its two chief earthy springs are the Georg-Victor-quelle, and the Helenen-quelle, and it has besides an iron spring. The Georg-Victor has 5·4 and the Helenen 9·7 grains of carbonate of lime. There is no lime sulphate, but the sulphates of soda and potash are ·6 and ·3 respectively. The Helenen-quelle contains 8 grains of common salt in 16 ounces and 6 of bicarbonate of soda, 10·4 of bicarbonate of magnesia, ·143 carbonate of iron, and 34 cubic inches of carbonic acid gas, while the quantities in Georg-Victor are ·06, ·49, 4·1, ·161 grain, and 33 cubic inches of gas. The third spring, Thalquelle, contains 6·67 common salt, 10 bicarbonate of lime, 9·8 bicarbonate of magnesia, ·1 carbonate of iron, and 33 cubic inches of gas. The water, specially the Georg-Victor spring, is much used in chronic catarrh of the bladder, incontinence of urine, in gravel, and other affections of the kidney.

VIII. Iron Waters (Chalybeate Springs).

Iron or steel waters are not the only mineral waters in which some form of iron is found. Indeed in nearly all mineral waters this ingredient exists, but in very many in such small quantity, while other ingredients are so conspicuous, that the character of the water can hardly be supposed to be affected by that metal. There is no stated amount of iron which entitles a spring to be classed as chalybeate, though those most successfully resorted to contain from $\frac{1}{3}$d to $\frac{9}{10}$ths of a grain of iron in the form of carbonate in 16 ounces. Some springs are classed as iron springs which contain barely $\frac{1}{5}$th of a grain in 16 ounces of water, but they are so because they have been found by the actual experience of cases to have the beneficial effects of steel waters. Indeed it is rather the experience of the value of the water in particular forms of disease than the actual quantity of iron it contains that determines how it should be ranked. What are called **pure iron springs** are those which contain but a few grains of dissolved solids, a salt of iron existing to some appreciable amount; **compound iron springs** contain moderate quantities of other salts, such as Epsom and Glauber's salts, common salt, sulphate of lime, besides being rich in carbonic acid gas. To this class some of the springs already named are entitled to belong, such as Franzensbad, Marienbad, Tarasp, Elster. We take the following list of springs containing iron from Braun, springs which we have already considered, and we note the amount of iron in the form of carbonate which each contains in grains per 16 ounces:—

Common Salt Waters (Table II. p. 929).

	Grains of Iron in 16 ozs.
Cronthal, Ischl, Mergentheim, Wiesbaden,	·04 to ·05
Adelheidsquelle,	·07

Gleichenberg,	·14 to ·18
Geilnau,	·16

The reason for the use of iron waters is that iron is a necessary ingredient of the blood (see pp. 216 and 816), and in certain conditions promotes the formation of blood. But the total quantity in the blood does not exceed 40 grains, and it has been estimated that in health the quantity taken up into the blood per day does not exceed 1 grain, though in some cases of poverty of blood, chlorosis (p. 235), 4 to 5 grains may be taken up and incorporated. The most useful springs will yield from ·14 to ·42 grain of iron in 16 to 48 ounces of mineral water. But food contains iron salts. It is, indeed, from the food that the continual renewal of iron to the blood takes place, flesh meat, yolk of egg, wheat, barley, and lentils, containing considerable proportions of the metal. When this condition of poverty of blood exists, it affects all the bodily functions, and the powers of digestion and assimilation are so enfeebled that full advantage is not taken of the food supplied, and so the condition tends to persist. Under such circumstances the change of air, and the general beneficial influences exerted upon the whole body by the life of the spa, have such stimulating effects upon the nutritive processes that there can be no doubt much of the benefit is due to quite other circumstances than the mere presence of iron in the water drunk. Besides that the presence of other ingredients of the spring, carbonic acid gas, common salt, &c., is stimulating to the stomach and bowels and tends directly to the improvement of the nutrition. It is, at any rate, plain that when such a small total quantity of iron exists in the blood, and such a small quantity is daily made use of, only small doses are necessary. If excessive doses be given, the excess is passed off in the motions as a sulphide of iron, blackening them, and is apt to irritate the stomach and bowels, to interfere with digestion, and to produce constipation. When small doses are given more is actually absorbed into the blood than when large quantities are taken. The conditions, therefore, in which iron springs are most likely to be useful are pretty plain. They are those in which one seeks to promote blood formation, those dependent upon poverty of blood. It has been found that iron springs are most useful in cases of poverty of blood quickly produced, for example, by loss of blood, by bleeding from the nose, or from wounds, by drain occurring from the blood owing to diarrhœa, suppuration, and other profuse discharges, in cases of chlorosis in young girls, and in poverty of blood dependent upon acute disease, in which cases they materially promote convalescence. Iron springs are also used in disorders of monthly illness, specially in its absence, in malarious conditions and poverty of blood due to residence in tropical countries, and in neuralgia, sterility, and impotency due to enfeebled conditions of general health. In such cases as these last the improvement is not so rapid, and is often best promoted by waters which, besides the iron, contain marked quantities of other ingredients like common salt.

It is chiefly in the form of carbonate that the iron exists, and this is the best form for administration. The presence of carbonic acid gas in the water keeps the carbonate of iron in solution, and when the water stands a yellowish rust is deposited.

If constipation be associated with the bloodless condition, a spring should be chosen which contains common salt, or Glauber's or Epsom salts to correct this condition, and if a pure iron spring causes costiveness or diarrhœa and indigestion, a change in a similar direction must be made, such as Marienbad, Franzensbad, Elster.

Iron springs are used for bathing, but it is not now believed that the iron they contain produces any effect upon the skin, or is absorbed from the bath. They have no further effect than baths of plain water, except what is due to the stimulating effect of any carbonic acid

VIII. IRON WATERS (CHALYBEATE SPRINGS).

Name.	Situation.	Altitude in feet.	Ingredients in grains per 16 ozs. Carbonate of Iron.	Carbonates of Soda, Lime, Magnesia.	Sulphates, Soda, Lime, &c.	Common Salt and other Chlorides	Carbonic Acid Gas in cub. in. per 16 ozs.	Remarks.
Alet	Aude, France							
Alexisbad [1]	Harz Mountains	1,350	·35	Only 3 grains other constituents.			10	
Altwasser [1]	Silesia	1,255	·3 to ·7	4·7	½ to 1		4 to 27	
Antogast	Badish Black Forest	1,585	·23	20 grs. other constituents.				
Arapatak	Transylvania		1·16 to 2·35	22 to 24			33	
Bartfeld	North Hungary		·67	16		5	45	
Bocklet (Stahlquelle)	Near Kissingen	620	·67	10	5¾	11	39	
Brückenau [1]	Bavaria	915	·09	1·8	¾		38	Hot.
Bussang	In the Vosges	Table water only. No establishment.						
Cheltenham	England		·88	6 grs. other constituents.				
Cudowa	Silesia	1,235	·2	13	5¼		33	Contains also arseniate of iron ·008 to ·012.
Driburg	Westphalia	633	·78	15	22		28	
Elster (see Table III.)			·35					
Flinsberg [1]	Silesia	1,550	·25	Only 2 to 6 grains other ingredients.			27	
Franzensbad	Bohemia	1,293	·3	See Table III.				
Freienwalde [1]	On the Oder		·17 to ·26				little	
Freiersbach	Black Forest	1,280	·7	6½	2		14	
Godesberg	Near Bonn		·2	12		7·3		
Gonten [1]	Appenzell Canton (Switzerland)	2,761	·33					
Griesbach	Baden	1,614	·6	13	8		18	
Harrogate [1]	England	420	Chloride of iron 1·32, carbonate 1·1.			43·9	2 to 2½	
Heinrichsbad	Canton Appenzell	2,410						
Hofgeismar	Hesse	328	·2 to ·4	Only 21 grs. other ingredients.				
Homburg (Stahlbrunnen). See p. 930.								
Imnau	Hohenzollern	1,430	·64	8	½	1¼	30	
Kainzenbad	Bavaria	2,480	See Table V.					
Kœnigswarth [1]	Between Franzensbad and Marienbad	2,000	·4 to ·65	Only 5 to 6 grains other ingredients.			30	
Liebenstein [1]	Thuringian Forest	1,000	·6	6	1½	nearly 2	32	
Liebwerda [1]	Bohemia	1,225	·17	Only 2·5 grains other ingredients.			22	
Lobenstein [1]	Principality of Reuss	1,500	·43					
Muskau [1]	Upper Lusatia (Prus.)	300	Sulphate of iron 1·52, carbonate of iron 1·38.		3½	½	traces	
Niederlangenau [1]	Glatz	1,137	·28	2½	Only 3½ grs. other constituents.		35	
Orezza	Corsica		·85	5			abundant	Traces of arsenic.
Petersthal	Baden	1,333	·35	15	6½	½	34	
Pyrmont	Waldeck	400	·37	10½	11	½	29	
Recoaro	North Italy	1,465	·23	5½	14½		18	Lukewarm.
Reinerz	Silesia	1,235	·29	12	½	$\frac{1}{10}$	35	
Rippoldsau	Baden	1,886	·9	12	8		15	
Santa Catarina	Upper Italy (3 miles from Bormio)	5,600						
Schandau [1]	Saxon Switzerland		·11					
Schwalbach [1] (Stahlbrunnen)	Nassau	900	·64	3½			50	
Shelfanger	Diss, Norfolk, Eng.		·29	2½	·46	·65		
Spa [1] (Pouhon Spring)	Belgium	1,000	·14	Total ingredients 3·9.			8	
St. Moritz	Switzerland	5,710	·2	8	2		31	
Sternberg [1]	Near Prague		·24	Total solids 4·7 grains.			8	
Tunbridge Wells [1]	Kent, England	300	·11					
Vichnye [1]			·95				6	
Wiesau	Bavaria	1,642						
Wildungen	Waldeck	740	·58	See Table VII.			18	

[1] Pure chalybeate waters; others are compound.

gas which may remain in the water after it is heated.

Antogast (1585 feet) is one of the Kniebis baths, which include also Freiersbach, Griesbach, Petersthal, and Rippoldsau. They all lie in the Black Forest, Duchy of Baden, and are reached from stations on the Baden Railway. They vary in the quantities of iron their springs contain, as Table VIII. shows, and they have the advantages of mountain elevation, forest air, and beautiful scenery. They are adapted for all cases of poverty of blood.

Bocklet (620 feet) is only 4 miles north of Kissingen, and the use of its waters is frequently advised after a course at Kissingen. Its spring is advantageous from the combination of common salt and carbonic acid gas with the iron. Bocklet itself is only a small village. Its atmosphere is healthy and invigorating, and from the absence of fashionable amusements it offers a pleasant quiet rural retreat for those who prefer a retired resort. It has a sulphur spring which also contains carbonate of iron to the extent of ·4 of a grain in 16 ounces. The steel springs are two in number, and contain about the same proportion of iron. There is good accommodation in the village as well as in the establishment connected with the springs. It is chiefly resorted to for female disorders.

Harrogate has already been considered under Sulphur Wells (see p. 944). It has also two chief iron springs, the Muspratt and the Tewitt. The latter is a pure chalybeate spring, containing ·135 grain carbonate of iron in 16 ounces. The Muspratt spring, the analysis of which is given on p. 943, is much stronger, and is given in doses of from 2 to 6 ounces three times daily, but it is much more apt to disagree than the water of the weaker spring. The use of these waters has been sufficiently indicated on p. 941.

Orezza is in Corsica, 20 miles from Bastia. "It is in a beautiful country and amidst forests. It is in great repute locally in cases in which iron is indicated, especially in chlorosis and some of the complaints of women, and is said to be a specific in malarious poisoning, which is common in many parts of Corsica, but only when it has not gone the length of producing engorgement of the liver or spleen. Its waters are largely exported. The season is short—from the middle of June to the 30th of August" (Macpherson). It may be used in cases of poverty of blood (anæmia) as a tonic table water.

Pyrmont has already been referred to in regard to its salt springs on p. 929. It was formerly much frequented and very fashionable on account of its iron spring. But it lies only 400 feet above the sea-level, and iron springs which have the advantages of a much higher elevation are now sought in preference, though its waters are well suited for cases where iron treatment is desired, and its arrangements and accommodation are excellent.

Schwalbach is one of the most popular and frequented of iron springs. It lies 951 feet above sea-level in a sheltered valley of the Taunus range, and may be reached by railway from Wiesbaden in an hour and a half. It is one hour's distance by road from Schlangenbad. While it has the benefit of mountain situation it is well sheltered, and its arrangements are excellent. "Everything that has been said of the effects of iron applies to Schwalbach, and there are few wells which answer in their effects to one's expectations better than these" (Macpherson). It has three chief wells—Stahlbrunnen, of which the analysis is given in the table; Weinbrunnen, with ·44 grain carbonate of iron in 16 ounces; and Paulinenbrunnen, with ·51 gr. carbonate of iron. The season is May to October.

Spa is one of the most accessible of continental baths from England. It is reached by a short branch from the railway from Brussels to Liège, the junction station being Pepinster, and the distance from Liège 17 miles. It lies in a beautiful valley of the Ardennes at an elevation of over 1000 feet, 20 miles from Aix-la-Chapelle. Sheltered from the north, it has a mild climate; the surrounding country is attractive; the bathing arrangements are luxurious; and riding on horseback is one of the favourite forms of exercise. It has no less than sixteen springs, the chief, Pouhon, being situated in the centre of the town. Mud-baths are also employed, the material being obtained from the peat soil in the neighbourhood of the town.

St. Moritz (5710 feet) as a health resort has been sufficiently spoken of on p. 796. Its steel springs are tolerably pure, and are pleasant from the abundance of gas they contain. Baths are also to be had. But the waters and baths are really secondary considerations in a residence at St. Moritz, the bracing effect of the mountain air and the magnificent scenery being the chief attractions for the large numbers who seek the restorative influences of this favourite resort.

Tunbridge Wells, 30 miles south of London, possesses a fairly pure steel spring. Its climate is healthy and bracing and its surroundings beautiful. Its waters are not taken advantage of to the extent they might be. Weber suggests that the addition of Selters or Apollinaris might make them more useful for some constitutions, because of the stimulating effect which the carbonic acid gas either of these table waters would supply.

IX. Iodine Waters.

A considerable number of the waters we have noticed contain minute quantities of iodine as iodide of sodium or magnesium, and also bromine in similar combinations. To the presence of

this ingredient much value was attached, especially in the treatment of scrofula in children, and in various other complaints. The springs which were specially classed as iodine or bromo-iodine waters were the Adelheids spring (p. 929), Dürkheim (p. 929), Hall (p. 929), Kreuznach (p. 931), Wildegg (p. 929), and Woodhall (p. 932). The quantity of the iodine compound is in every case so small that it is not now believed that it can produce any perceptible effect upon the body, except perhaps in the case of Woodhall. The waters are usually rich in other saline ingredients, to which their good effects are now attributed, and they have accordingly been noticed elsewhere.

X. Arsenical Waters.

What has been said of iodine waters is equally true of arsenical waters. The presence of minute quantities of arsenic is found in several waters, but the chief are La Bourboule (p. 940), St. Dominique (of Vals), and Mont Dore (p. 937). It has been estimated that to get a medicinal dose of arsenic 4 to 8 pints of the water would require to be taken daily, and as a rule the effect of this ingredient is scarcely calculated upon.

Court St. Etienne water, from a spring near Waterloo, in Belgium, discovered in 1878, is said to be one of the strongest and most permanent of arsenical waters. Tichborne's analysis gives ·083 grain arseniate of soda in 16 ounces, and this amount of arsenical salt is associated with less than 2 grains of other ingredients, so that it might be used as a pure arsenical water in cases where arsenic seemed indicated (see p. 823).

The Whey-cure.

The whey-cure is a method of treatment adopted at many health resorts, the whey being either sipped alone at a temperature of about 105° F., while the patient takes gentle exercise, or being added to the mineral water of the resort. In the former case not less than a pint daily is the quantity consumed, and from 4 or 6 pints are the largest quantities ordered. The whey is taken in the early morning, and breakfast is not taken till after an interval of an hour or more. In the chief whey establishments goats' milk is used for the production of the whey. The nature of whey has been explained on p. 550. It is milk deprived of its casein or curd, and most of its fat or butter. It thus contains a small quantity of albuminous material, a little fat (the clearer it is the less fat it contains), the sugar of milk, and the salts of milk (p. 551), chlorides, sulphates, and phosphates. The value of the whey is attributed partly to the sugar, and partly to the salts. The whey has a slight opening effect on the bowels, but is also apt to cause dyspepsia and catarrh of the bowels. The whey-cure is specially ordered for consumptive patients, and for persons with much cough, and irritation of the windpipe and large bronchial tubes. But these are just the cases which are now sent to mountain resorts, where indeed the chief whey establishments are, and the improvement effected is mainly due to the fresh mountain air. Braun doubts whether whey is not actually less useful than well-adapted courses of mineral waters, like those of Carlsbad or Marienbad, which stimulate stomach and bowels, and aid the appetite and digestion without producing catarrh.

Whey is to be had at nearly every mineral spa, but those which have a special repute in this way are stated below.

Alexisbad (p. 949).

Arco, in the Southern Tyrol.

Baden, near Vienna (p. 943).

Driburg (p. 949).

Elster (p. 934).

Ems (see p. 940).

Engelberg (canton Unterwalden, Switzerland), 3180 feet above the sea, reached from Lucerne.

Gais, in the canton Appenzell, 3064 feet above the sea.

Gleisweiler, 1000 feet above the sea, one hour from Landau in the Lower Palatinate.

Heiden, in canton Appenzell, Switzerland, 2645 feet above sea-level.

Heinrichsbad (p. 949).

Interlaken, Switzerland, 1863 feet above sea-level.

Ischl (p. 929).

Kreuth (p. 929).

Liebenstein (p. 949).

Meran (p. 797).

Montreux, 1186 feet above the sea, on the Lake of Geneva, near Vevey.

Rehburg, in Hanover, which has also saline and iron springs.

Reichenhall (p. 929).

Reinerz (p. 949).

Roznau, in Moravia, 1200 feet above sea-level.

Salzbrunn (p. 937).

Schlangenbad (p. 926).

Soden, in Nassau (p. 929).

Streitberg, in Bavaria, 1800 feet.

Waggis, at the base of the Righi, on Lake Lucerne, at an elevation of 1434 feet.

Weissbad, canton Appenzell, Switzerland, 2320 feet above the sea.

Most of these places, specially those of Switzerland, are favourite health resorts in summer, and many of them suitable for consumptive patients.

The Grape-cure.

The grape-cure has been referred to on p. 576, and in speaking of Meran on p. 797. Taken in quantity on an empty stomach grapes act upon the bowels, stimulate change of substance, and at the same time supply sugar and salts to the blood. From 1 to 8 pounds are consumed per day, partly taken before breakfast, and partly throughout the day. They are used for their opening effect in cases of sluggishness of abdominal organs and corpulence, and in lung affections for their stimulus to the general nourishment of the body. Braun says of this method of treatment, "All, however, that has been said of the whey-cure applies still more to the grape-cure. Dyspepsia and catarrh of the bowels are constantly the results of the treatment, and a case seldom occurs in which the object could not have been better obtained by means of courses of mineral waters without any of these injurious symptoms."

The best-known resorts for the grape-cure are named below:—

Arco, in the Southern Tyrol, 288 feet above the sea, three-quarters of an hour from Riva, on Lake Garda, and two hours' journey from the Mori station. The season is from October to May, and the place is well suited for cases of consumption.

Bex (see p. 929).

Bozen, in the Tyrol, a town of 10,000 inhabitants, a station on the railway from Munich to Verona. Meran is on the same line.

Dürkheim (p. 929).

Edenkoben, in the Haardt Mountains.

Gleisweiler (p. 951).

Grünberg, in Silesia. **Meran** (p. 797).

Kreuznach (p. 931). **Montreux** (p. 951).

Rheinfelden, in the canton Aargau, Switzerland, at an elevation of 866 feet.

Vevey, canton Vaud, Switzerland; elevation 1263 feet. On the Lake of Geneva.

Any one desiring further details of mineral baths and wells, &c., should consult *Curative Effects of Baths and Waters*, by Dr. Julius Braun, translated by Dr. Hermann Weber, *The Baths and Wells of Europe*, by Dr. John Macpherson, or *The Mineral Waters of Europe*, by Drs. C. R. C. Tichborne and Prosser James.

Section XI.—THE MEDICAL USES OF ELECTRICITY.

The Medical Uses of Electricity.

Electricity has of late years been much employed in the treatment of disease. The benefits derived from it when it is properly employed are in many cases of a very remarkable kind, and for many diseases it affords almost the only hopeful means of treatment. There are now many workers in this department of medicine, and the employment of this agent is becoming yearly more and more extended. Still, the effects of electricity are not well understood, and much remains to be done before this agent, powerful though it undoubtedly is, can become commonly used. It ought to be said that the regular employment of electricity by medical men has nothing in common with the use of magnetic appliances, electropathic belts, and so on, which, so far as is at present known, are entirely valueless. It is the electric current, as generated by the usual forms of batteries, to which reference is made in this section. Two kinds of current are chiefly used: (1) that directly obtained from cells, associated together in the form of a battery, which is a **constant current**, and may be allowed to flow through the part of the body to be acted upon for a certain length of time continuously, or may be interrupted slowly or quickly by a suitable appliance; and (2) that obtained from a coil of wire, in the immediate neighbourhood of another coil through which a current from one or more cells is passing. The first is the ordinary **galvanic current**, or **constant current**; the second is the **induced current**, or the **Faradic current**.

One of the chief purposes for which electricity is used is for stimulating paralysed muscles and nerves. In cases of paralysis from nervous disease, or from lead-poisoning, or from the effect of diphtheria, or in cases of paralysis of a nerve from cold, for example paralysis of one side of the face, treatment by electricity is one of the chief methods of cure. The current from battery or induction-coil is applied directly to the affected muscles or nerves. Holding the handles of the battery or induction-coil so as to permit the elec-

tricity to flow through the body is in no case of much use. The wires from the coil or battery are usually connected with button-like pieces of brass attached to wooden handles, and covered with chamois leather. The leather is soaked in salt water, and the skin over the part to be acted upon is also well moistened with the salt water. These handles with their brass ends are called **electrodes** or **terminals**, and the actual shape and size of the brass piece depends upon the part to which it is to be applied. One electrode is usually placed on an indifferent part of the body, the nape of the neck or some part of the back, and the other is placed over the part to be acted on. The current is then allowed to pass; and if from a battery it may be allowed to flow continuously by keeping the electrodes steadily applied, or it may be interrupted and sent on again by lifting one electrode and then reapplying it. It is when interrupted in this way that the current is most stimulating; and this method of application is employed in paralysis of muscle or nerve. The most stimulating current is the induced current, since it is not a continuous stream but a rapid series of shocks. When a paralysed limb is being treated it is of little use to pass the current through the whole limb at once, but the limb must be gone over bit by bit, each muscle being in turn stimulated to contract, the movement produced being quite visible, and for this purpose anatomical knowledge of the position of the various muscles and the nerves supplying them is of course required.

The stimulating effects of the induced electrical current are made use of in some skin diseases, in some chronic scaly diseases for example. The same effects are brought into play to stimulate the growth of hair on bald patches, such as from the disease of hair known as alopecia areata (p. 329). In such a case one electrode of the kind described, well moistened, is placed on the nape of the neck, and the second is in the shape of a fine wire brush, with which the bald spot is brushed.

Electricity may be employed for the relief of pain, neuralgia for example. For this a weak constant current is used, the electrode connected with the negative pole of a battery is placed, well moistened, over the nape of the neck, and that connected with the positive pole, also well moistened, over the painful spot, and the current allowed to flow steadily for a few minutes. Ovarian pain (p. 507) is thus frequently successfully treated. Painful rheumatic joints may be relieved in a similar way, and sometimes by the induced current applied over the skin of the affected joint by the dry wire brush. The passage of the constant current through a chronic rheumatic joint is often attended by much relief, not only by the soothing effects of the current, but also because it induces beneficial changes in the nutrition of the joint, leading to the renewal of thickenings and swellings.

In hysterical affections electricity employed in association with massage (p. 772) is one of the most important of modern methods of treatment.

Electricity is becoming more and more made use of in nervous affections connected with the brain and spinal cord, and in mental disease, especially in melancholia, there is a great future in store for this method of treatment. The writer has had in his own experience a few very remarkable instances, where complete removal of the mental disorder followed the employment of a weak constant current of electricity to the brain. In such cases, of course, the remedy requires to be very cautiously applied, and could not be ventured upon by any one not well acquainted with the proper method of application.

In surgery the electrical current is made use of for the removal of small tumours and growths. In such cases a current is used sufficient to bring platinum wire to a red heat, the growth being destroyed by being touched with the glowing point, or the tumour being removed by being encircled with the red-hot wire. The advantage of electricity over the ordinary cautery being that the platinum point or wire may be properly adjusted cold, and then the current sent on to make it hot.

In cases of aneurism (p. 244) needles, connected with a battery, are passed into the sac of the aneurism, and the electric current by decomposing the blood in the tumour promotes the formation of a clot.

In eye surgery electricity is made use of to remove pieces of steel from the eye by rendering a steel point magnetic.

These are but a few illustrations of the value of this physical agent in the treatment of disease. Many more might be given. But so much special knowledge is required to enable one to employ such an agent with success and without risk, that no advantage is to be gained from entering into fuller details.

Section XII.—THE USE OF ANIMAL EXTRACTS IN MEDICINE.

Within the last few years great additions have been made to the number of remedies employed in the treatment of disease. In two directions specially valuable progress has been made. One of these is in the employment of preparations made from certain organs or tissues of the lower animals, and the other is in the extension of a process, akin to that of vaccination, by which a person is protected against, or cured of, an infectious disease, by injecting into his body, under the skin, some of the blood obtained from an animal previously made refractory to the particular disease in question.

The former class of remedies is called **animal extracts**, and the latter class **anti-toxins**, and the reason of these terms will be immediately apparent.

Animal Extracts.—Pepsin and pancreatin, described on pp. 845, 846, are animal extracts. They may be extracted, the one from the stomach, the other from the pancreas or sweetbread, of the pig or calf, by soaking pieces of the organ in glycerine or alcohol. They are ferments whose action is understood, and can be carried on outside the body as well as within it. But the new variety of animal extracts, which may be made also by steeping pieces of the desired organ in glycerine, produce their effects only when introduced into the body. Their action is not, so far as is known, due to ferments, it cannot be imitated outside of the body, and their effects are best seen in diseased conditions of the body, when they seem, in a manner not yet understood, to assist some function of the body not being properly carried on. The typical illustration of the use of such extracts is a disease called **myxœdema.** This affection seems to be dependent on disease of the thyroid gland in the neck. In it there is marked increase in the general bulk of the body. The skin is swollen as if it were dropsical, but the swelling is firm and solid, and does not pit on pressure as dropsical swellings do. The skin becomes dry and rough; the face loses its expression; hair falls out, so that the patient becomes bald; the utterance becomes slurring; the quality of the voice altered; movement becomes slow, and also thought; memory defective. The temperature of the body is lowered. These changes go on slowly, so slowly as to take years to become very obvious. In such patients the thyroid gland is diseased or atrophied. The symptoms of the disease may be produced in animals by the removal of this organ. Now, this disease was believed to be incurable, till its relation to the thyroid gland began to be suspected. The first result of this idea was the suggestion of grafting the healthy thyroid gland, just removed from an animal, into the body of the patient, in the hope that if it could be done successfully, the transplanted organ might perform the function the diseased organ had failed to do. Success was obtained. The next step in advance was made when it was found that excellent results followed the administration to the patient, by the mouth, of the fresh thyroid gland of a calf or lamb, finely chopped up. Glycerine extracts were then made use of, and proved of equal value. The gland is now used mainly in the form of tabloids, made of the dried gland compressed. These keep very well, and, swallowed whole, are practically tasteless. In a pronounced case of myxœdema, the effects of the treatment are of a most amazing kind. In a few days the solid swelling begins to diminish with great rapidity, and all the other symptoms to disappear. Even the hair is restored. But the remedy must be given with care, for its effects are sometimes alarming. Nausea, loss of appetite, loss of strength, and indeed great prostration are quite common results if the treatment be carried out too rapidly or too long. But, with care in the administration of the remedy, no evil need be feared. From a quarter to a half of the fresh gland may be given daily, and the dose gradually increased as seems desirable. The tabloids are a very convenient means of administration, at the beginning half a tabloid being given twice or thrice daily, and the dose being gradually increased. After all symptoms of the disease have disappeared the treatment may be stopped for a time, but it is, as a rule, necessary to maintain the condition of health by a short course of the treatment at intervals.

Thyroid extract or tabloids have been found valuable in other disorders. In the disease called cretinism (p. 211) equally remarkable results have been obtained. The remedy has been successfully employed in certain skin diseases, specially psoriasis and lupus, in obesity, and in a very rare disease called **acromegaly**, characterized by the enormous size to which the hands and feet grow. In some forms of in-

sanity benefit of a most remarkable kind has been obtained by thyroid treatment.

Now, these results opened up a new departure in the treatment of disease. The medicinal value of other organs, used raw, or in extract or tabloid, was investigated, and with some result. Before the discovery of the use of thyroid in myxœdema, Brown-Séquard of Paris had advocated the use of certain organic extracts in nervous disorders, and in such diseases ovarian substance and testicular substances, also obtainable in tabloid form, have since been successfully administered.

In certain forms of bloodlessness the use of the red marrow of bone has been suggested and favourably reported on. It also may be obtained in tabloid form, but it is easily procured fresh from the butcher. If one of the short bones of a lamb or calf be split in its length, the red marrow is lifted out by a spoon. It may then be made up with jelly, or, with salt and spice, spread on thin bread and so eaten. Extract of suprarenal capsules, of spleen, of the thymus gland and pituitary body have also been added to the list of remedial agents. From brain tissue, powders called cerebrin and cerebrinin have been prepared, whose value in headache, sleeplessness, and other nervous disturbances is considerable.

Anti-toxins.—In Section XIII. of the first part of this work the relation between living organisms and disease has been pointed out. Some account has also been given of Pasteur's work, and specially in the search of means to combat such diseases. It has been explained, on p. 392, how Pasteur was able to prepare an inoculating fluid which would protect animals against splenic fever. Animals which have thus been protected against an infectious disease are said to be **immune**, and the process is called **immunization.** It is well known how the latest triumph of Pasteur was obtained in the investigation of hydrophobia. From the spinal cord of animals who had suffered from hydrophobia, he was able to prepare a fluid, which, injected under the skin of persons who had been bitten by a mad dog, protected them from this disease. Such a preparation is called an **anti-toxin**, from the Greek words *anti*, against, and *toxikon*, poison. Some years ago Koch, pursuing his investigations into tuberculosis, the disease of which consumption is a variety, due to the action of an organism, the tubercle bacillus, believed he had discovered a remedy for the disease. The remedy was obtained by making a pure cultivation of the tubercle bacillus, and straining off the fluid in which it had been grown. This fluid injected under the skin of tuberculous patients, it was believed by him, would cure the disease. His anticipations have not been fully accomplished, though the preparation thus obtained has, nevertheless, proved to be of great value. It has been found, for instance, that certain marked effects were produced in patients who suffered from any form of tuberculosis, when this substance, called **tuberculin**, was injected, and that they did not follow in the case of persons unaffected by tubercle. The same has been found true in the case of animals. Now tuberculosis is one of the commonest of diseases in cattle, and from cattle it may be communicated to human beings by the use of tuberculous meat, or by the use of milk from tuberculous cows. But often ordinary methods fail to indicate when an animal is tuberculous. The use of Koch's preparation will enable tuberculosis to be discovered in cattle, and so dairy-farmers and stock-raisers have had put into their hands a valuable means of preventing diseased animals being added to their stock.

But though an anti-toxin which shall render a person immune to consumption has not yet been found, success has been achieved in the case of other diseases. The chief instance is that of diphtheria. Why does one attack of an infectious disease protect the patient against a second, or, at least, render the patient much less susceptible? The theory is that the infective organism produces certain substances, in the course of its activity, in the blood and tissues of the patient, which act as poisons to the tissues, but that other substances are also produced, in time, which are antagonistic to these poisonous substances and so arrest their further action. Now if these antagonistic substances could be produced at will, and injected into the body of a person who had been exposed to the particular infection, or was suffering from the disease, the poison of the disease would be antagonized and the patient cured. This is briefly the theory of the anti-toxic treatment of infectious disease. The result has been successfully achieved in the case of diphtheria, the anti-toxin being prepared from the blood of a horse rendered immune. In thousands of cases this remedy has been employed, with the result of a great reduction in the mortality from the disease.

Anti-toxins have also been prepared for erysipelas, tetanus, certain forms of blood-poisoning, and for the poison of snake-bite.

PART IV.

BANDAGING: ACCIDENTS AND EMERGENCIES: FIRST AID TO INJURED: MINOR SURGERY, AND MEDICAL AND SURGICAL APPLIANCES.

SECTION I.—BANDAGING.

The Uses of Bandages:
- *Rules for Bandaging;*
- *The Material for Bandages;*
- *Method of Applying the Bandage.*

Varieties of Turns for the Bandage:
- *The Simple Spiral;*
- *The Reversed Spiral;*
- *The Figure-of-8.*

Bandage for the Hand and Arm.

Bandage for the Fingers and Thumb.

Bandage for the Shoulder:

- *The* T *applied to the Chin and Head.*

Bandages for the Head:
- *The Capelline and Twisted or Knotted Head Bandages;*
- *Simple Bandage for the Head; the Shawl Cap.*

Starch and Plaster of Paris Bandages.

The Triangular Bandage:
- *Its Use as a Sling;*
- *Its Application as a Hand, Arm, Shoulder, Chest, Back, Foot, or Knee Bandage;*
- *Its Application to the Groin.*

The Knotting of Bandages:
- *The Granny and Reef Knots;*
- *The Clove Hitch.*

The Uses of Bandages. — Bandages are employed for a variety of purposes. One of their chief uses is to secure dressings or splints. Another is to give support to a limb or to restrain its movements, or to exert pressure upon it to aid in restraining bleeding at some point, or to promote healing as in the case of ulcers, or to aid in the removal of swelling. In these latter cases the bandage must be applied with a considerable degree of tightness, and great care must be exercised that the bandage is evenly put on, and that the tightness with which it is drawn does not give rise to disturbance of the circulation by undue and irregular pressure. This is a point well worthy of particular attention. Suppose the arm is being bandaged from the hand well up over the upper arm. The arteries which carry the blood down the limb are for the most part deeply seated and well protected by muscles, so that they are practically unaffected by any ordinary degree of pressure on the surface. But many of the veins which carry the blood back to the heart up the limb run immediately under the skin, and will be pressed upon considerably by a bandage applied round the arm. Suppose such a bandage applied loosely from the hand up near to the elbow, and suppose when the elbow is approached the bandage is pulled much more tightly, what is certain to be the result? The veins near the elbow will be compressed, the blood will flow less easily along them at that point than it does lower down where the pressure is less. The consequence will be that the blood will be hindered in passing up from the hand; and as blood is all the time being carried

EMERGENCY METHODS OF CARRYING INJURED PERSONS.

down to the hand in the arteries, which are unaffected, the veins in the forearm and hand below the tight turns of the bandage will become swollen and gorged with blood. The pressure of blood in the veins will become so great that fluid will be pressed out of the finer vessels into the surrounding tissues, and the hand will become swollen, puffy, and dropsical, while much pain will be experienced. If the tight turns of the bandage are now loosened, the veins will again offer a free passage to the blood, the activity of the circulation will be restored, and the swelling and pain will gradually subside and disappear. Now the results that have been described are exceedingly commonly witnessed as the result of bad bandaging, and it may take days for a hand to recover from the effects of a bandage thus improperly applied. What are the means of preventing such a state of affairs? Bandage loosely, one might say; but a loose bandage may be useless. The proper means of preventing it is to bandage *uniformly*, not to bandage tightly here and loosely there, but to begin with the requisite degree of tightness *at the very extremity of the limb*, and to bandage so evenly and regularly upwards. If any difference is permitted, it should be in the direction of allowing a somewhat less degree of tightness to be given to the turns of the bandage as they pass up. Any required degree of tightness may be given to the turns provided it begins from the extremity. For in such a case the veins are uniformly compressed from below up. They are really made channels of smaller diameter throughout. This does not hinder the return of blood; it simply causes the flow along the narrower channels to be faster than it would have been along the wider ones. But wherever a wide channel suddenly becomes narrowed, then the current becomes impeded and stagnation tends to arise.

Rules for Bandaging.—The first rule then in bandaging a limb is, *Never let the bandage be tighter high up the limb than it is at the extremity; apply it firmly and evenly at the extremity, and let it be carried up uniformly*, if anything allowing it to be a little easier as one proceeds. Now if this be understood, the reason of several rules regularly followed will be apparent. Suppose one has to bandage the upper arm. If a bandage be rolled round the limb simply at the place where it is immediately required, it is plain that the veins at this place will be compressed if the bandage is at all tightly applied, and the forearm and hand will swell. The rule, therefore, is, begin the bandage at the hand and proceed regularly up the limb till the part is reached which one specially desires to cover. We may therefore state as a second rule, that *if a bandage requires to be tightly applied in the course of a limb, the bandage must be begun at the extremity.* Of course if the bandage is to be applied quite loosely it is not necessary to begin at the extremity. It is specially necessary to follow these rules when the bandage is applied to secure a splint, since it must be tight enough to keep the splint in accurate position, or to keep a pad firmly applied over a wound for the arrest of bleeding. A good illustration of the support a properly-applied bandage gives to the circulation is in the case of varicose veins of the leg. The great swelling, dropsy, and pain may be almost entirely removed, at least very greatly relieved, by a bandage being put on with considerable tightness from the toes upwards.

When it is desired to exert very considerable pressure upon a part for a length of time, or when it is desired to keep a limb or a joint motionless for some time, this may be done without the use of splints by stiffening the bandage with starch or plaster of Paris in a way to be described.

The Material for Bandages usually consists of strips of unbleached or bleached calico, linen, flannel, or of muslin, or open web, crinoline or cheese-cloth. Elastic bandages and india-rubber bandages are in use for particular cases. The material should be torn into the strips of the requisite breadth; they should have no hem or edging, as this would prevent them stretching equally in all directions. The strips should be rolled up for use into firm **rollers**. A roller bandage is usually 6 yards long, but may be 8 or 12 yards. They are of different breadths according to the part to which they are to be applied. The commonest size is $2\frac{1}{2}$ and $3\frac{1}{2}$ inches, the former being the size suited for the arms and head, the latter for the legs and groin. For the chest and abdomen a width of $4\frac{1}{2}$ inches is best. For the finger the strip should be $\frac{3}{4}$ in. wide.

Method of Applying the Bandage.—Lay its *outer* side against the part, and let it be unrolled no more than 3 or 4 inches in advance. In the case of bandaging a limb the person should stand opposite the patient and begin on the *inner*, not the outer, side of the limb carrying the bandage from the inner side outwards over the limb.

Varieties of Turns.—There are various methods of making the turns of the bandage so

that they lie smoothly and press equally. The **simple spiral** is that form in which one turn simply overlaps the previous one to about half its breadth. This is the turn with which one very often begins a bandage, but it cannot be carried on very far, because the inequalities of the limb, the rapid thickening of the arm from the wrist upwards, for example, prevent each

Fig. 339.—The Reversed Spiral Bandage.

turn lying closely and evenly over its neighbour. A second kind of turn requires then to be used, called the **reversed spiral**. It is shown in its application to the arm on Fig. 339. As soon as it becomes necessary to make use of the reverse, the thumb of the left hand, which is supporting the limb, is placed on the lower edge of the last turn to fix it. The upper border of the turn is then folded down by turning the roller over in the hand, the roller being held quite slack while this is done. The roller is then carried round the limb till it comes opposite the place where the reverse was made and the manœuvre is repeated. So one reverse after another is made, so long as is necessary. The position of one reverse should be accurately in line with its neighbours as shown in

Fig. 340.—Figure-of-8 Bandage.

the figure; and if the bandaging is well done it looks exceedingly neat and tidy. When the enlargement of the limb is too great to permit even the reverse to lie evenly a third variety of turn is resorted to, the **figure-of-8**. This turn is required to cover joints such as the ankle, elbow, and knee smoothly. It is shown in its application to the elbow in Fig. 340. The bandage is carried alternately up and down the limb; the figure shows it after it has been carried up the limb and is on the point of being brought down. A figure-of-8 loop is actually produced. To do this turn successfully the loops should be made wide, the bandage being carried in a good slope upwards, and then down. When completed the bandage is hardly distinguishable from the ordinary reverse. (Compare Figs. 339 and 340.) Now these varieties of turn may all require to be used in the course of applying one bandage to a limb, the expert using one turn or another as is most suited to the shape of the limb, and producing as a result a firm, well-fitting, and neat-looking piece of work. The figure-of-8 bandage requires twice as much material to cover a limb as the simple spiral, and it is generally limited to turning round joints. When it is desired to cover the heel or elbow alone this is the turn adopted, the end of the bandage being laid over the point of the heel or elbow. The first turn would simply surround the joint, then starting from this the loops would gradually widen out, covering the joint as they proceeded, the loops crossing in front.

Bandage for the Hand and Arm.—A bandage $2\frac{1}{2}$ inches in width is used. Begin by laying the end across the back of the hand, the outer surface being next the skin, carry the bandage round the root of the little finger to the palm, across it, passing between the thumb and forefinger, where it meets and fixes down the end. From here the bandage is carried across the back of the hand upwards to the wrist, round the front of the wrist, and when it reaches the thumb side of the wrist it is carried again across the back of the hand but *downwards* towards the root of the little finger, round to the palm, which it again crosses to the space between the forefinger and thumb, from which it is again carried upwards to the wrist. This is a figure-of-8 turn, and several such turns are taken, each overlapping the other at a proper distance, and the turns being drawn pretty tight, till the palm and back of the hand are covered. It is well to put a little cotton-wool in the palm before the turns are made. Two or three simple spiral turns are then made from the wrist upwards, till it becomes necessary to use the reverse; at the elbow the turn is changed to the figure-of-8, and when it is covered, the simple spiral aided by a few reverses will carry the bandage well up towards the arm-pit. Before the turns are made round the elbow, a little piece of cotton-wool should be placed on the

bend of the elbow and another small piece on the inner edge of the joint, to protect the bony edge. Of course it may not be necessary to carry the bandage farther up than the lower edge of the elbow joint.

Bandage for the Fingers.—For the fingers a bandage ¾ths of an inch broad is required. Lay the outer surface of the bandage on the front of the wrist, carry it once round the wrist

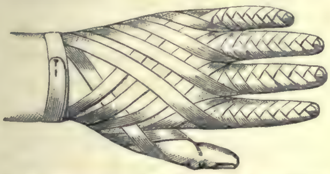

Fig. 341.—Reversed Spiral Bandage for Fingers.

to fix it, passing over the thumb side of the wrist first. When it comes round to this position again, carry the bandage across the back of the hand and right up to the tip of the finger with a few turns. From the tip slowly return down the finger, each turn overlapping the other to the proper extent, reverses being used, till the root of the finger is reached. Then take the bandage across the back of the hand to the wrist and fix it there by one or two turns. If more than one finger requires bandaging, after returning the bandage to the wrist and passing it once round, take it across the back of the hand again to the next finger, and treat it as before. In this way each finger may be bandaged with the same roller. The thumb is treated in a similar manner. This is shown in Fig. 341. One finger is shown in Fig. 342, bandaged with a few simple spiral turns, without any reverse.

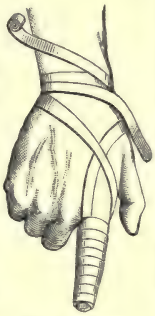

Fig. 342.—Spiral Bandage for Finger.

To bandage the thumb fix the roller by a turn round the wrist, then carry the bandage straight to the tip of the thumb, make one or two turns round the tip, and then descend by reverses to the first knuckle joint. Here the kind of turn is changed in order to cover the ball of the thumb properly. The bandage is carried across the back of the hand, round the wrist, then up round the ball of the thumb, across the back of the hand once more, round the wrist, again up round the ball of the thumb, and again down to the wrist, making a series of figure-of-8 loops, till the whole is covered in. Fig. 343 shows this arrangement, but without showing the tip of the thumb covered. In many cases when it is desired to cover only the ball of the thumb, the bandage to the tip is dispensed with.

Fig. 343.—Figure-of-8 Bandage for Thumb.

Bandage for the Shoulder.—This bandage is called the spica of the shoulder. A few turns of the roller are taken round the upper arm to fix the bandage, which is then carried up in front of the shoulder, over which it passes high up, then across the back to the opposite arm-pit,

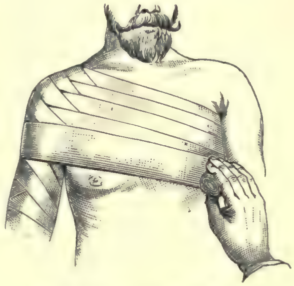

Fig. 344.—Spica of the Shoulder.

where it passes under the arm and over the front of the chest to the top of the shoulder again. Here it is turned down and passed under the arm-pit from which it started, and is brought up in front as at the beginning. Another turn of the course described is taken, and another and another, each turn partially overlapping the one preceding, and each coming lower and lower till the whole shoulder is covered in, when the bandage is finished off by a turn or two round the chest. This, it will be seen, is simply a figure-of-8 bandage. This is the usual method. A little cotton-wool is placed in both arm-pits to avoid chafing by the turns of the bandage. Fig. 344 shows the appearance of the shoulder when the bandage is finished. But in this particular instance the bandaging of the upper arm has been begun from behind, and the bandage has been brought round the outer side of the arm, carried straight across the chest to the opposite arm-pit, carried under it across the back to the top of the shoulder to be covered, then down in front to the arm-pit from which the bandage started, under it and round the back of the arm, and thence across the chest as before.

Bandage for the Foot and Leg.—A 2½-inch roller is used. The foot and leg are bandaged in a way similar to that described for the hand

and arm. Place the end of the bandage on the sole of the foot, carry the bandage up on the inner side of the foot and across the back to the outer side of the ankle, carry it round the ankle, and back across the foot to the outer side at the root of the little toe, down across the sole, and up again on the inner side. This prevents the bandage slipping. Then carry the bandage down the foot with reversed spirals till the heel is reached. There it is carried firmly up the inner side of the instep, and when it reaches the front it is taken round the ankle. The heel is thus not covered in at all. From the ankle the bandage is carried up the leg, by simple spirals up the small of the leg, and then by reversed spirals up the calf, and finished off below the knee-pan (Fig. 345). If the heel is to be covered it may be done by loops of the figure-of-8 turn. When

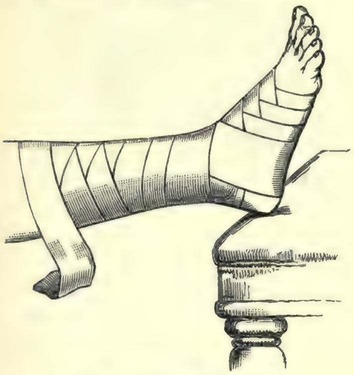

Fig. 345.—Foot and Leg Bandage.

it is necessary to cover the knee the figure-of-8 is also used. The combination of simple spiral and reversed spiral will carry the bandage up the thigh.

To cover the heel only, a broad bandage 3 inches or more is needed. Lay the end of the roller on the front of the ankle, and carry the bandage round the outer side, passing it over the point of the heel, which should accurately rest on the middle of the bandage. Complete the turn by bringing the bandage up the inner side of the heel to the front. The roller is then carried in figure-of-8 loops round the ankle, then across the back of the foot to the outer side of the sole, across it, up on the inner side; and it is then slanted upwards round the ankle again. Each turn half overlaps its neighbour, and thus the bandage passes up the small of the leg on one side and down towards the toes on the other till the whole joint is covered in.

Bandage for the Groin.—A bandage $2\frac{1}{2}$ to 3 inches wide is required. The groin is covered by a series of figure-of-8 loops like the shoulder. The arrangement is called the **spica of the groin.** It is shown in Fig. 346. Two or three turns, simple or reversed, are taken round the top of the thigh, passing from within outwards. The bandage is then carried up to the groin of the same side and outwards round just below the top of the haunch-bone to the back, across the back to the opposite side, and then obliquely downwards in front to the top of the thigh where the bandage began. It is passed round the outer side of that thigh and across the back of it, and is brought up between the legs, and again taken in a sloping direction up the groin, to pass round the back as before. Each turn only partially overlaps its neighbour on its lower side. Care must be taken that the first turn is not carried so high up as to slip off the haunch-bones on to the abdomen. A double spica will cover both groins. For this a very long bandage would be necessary, and when it reached the side of the body opposite to where it started it would be carried down the groin on that side to the inner side of the thigh of the same side of the body, round the back of the thigh, and then up across the body to the side from which it started. The double spica is, however, seldom used.

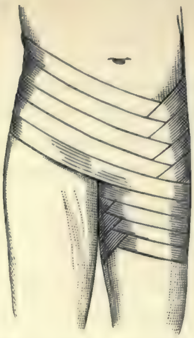

Fig. 346.—Spica of the Groin.

To Bandage the Breast use a 3-inch roller. Begin in front and carry the bandage round the chest below the breasts, passing towards the *sound* side. Two or three turns are made to fix it, and then it is carried upwards in a sloping direction over the lower part of the breast to be covered to the shoulder of the opposite side, over which it is passed. It is then brought across the back to the arm-pit of the affected side, and is carried once round the chest to fix the upward turn by overlapping. When it comes to the front again it is carried upwards again, half overlapping on its upper side the previous upward turn, and passing over the shoulder is again brought to the front by the

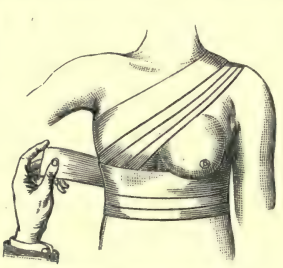

Fig. 347.—Bandage for the Breast.

arm-pit, makes another complete horizontal turn round the chest, and then a third turn is taken over the shoulder. So the process is repeated till the whole breast is covered in (Fig. 347).

The Chest is bandaged by a series of spiral turns from below up; and the bandage is finally carried over the shoulders, like braces, to keep the whole from slipping.

The T Bandage (Fig. 348) is used for fixing dressings close up between the legs. Take a strip of calico 1½ yard long and 3 inches wide. It is used for encircling the body, and is represented by the horizontal part of the **T**. To the centre of it attach a similar strip 1 yard long, in the position of the leg of the **T**. The first portion is placed round the body and fastened in front, the other piece hanging behind is brought up between the legs, fixing the dressings, and is fixed to the front of the encircling band.

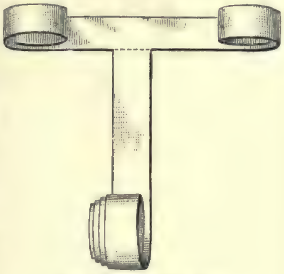

Fig. 348.—The T Bandage.

The Double T is shown in Fig. 349. The encircling band is the same as before. For the limb of the **T** a bandage double the width, or nearly so, is taken and torn up to within 5 inches of one end. This undivided piece is sewed behind to the band that passes round the body, and the two tails are carried up between the legs to the front. It acts like the previous bandage, but is more easily adjusted than the single tail.

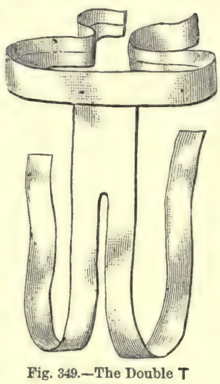

Fig. 349.—The Double T Bandage.

The Four-tailed Bandage is made with a piece of calico 1½ yard long and 6 inches wide. It is torn from each end up to within 3 inches of the centre. Thus there is a centre piece with four tails.

For the Chin this bandage is used by placing the middle of the centre piece on the point of the chin, and carrying the lower tails up the side of the head, tying them on the top, while the upper tails are carried backwards to a little above the nape of the neck and tied there. The ends of the two sets of tails are then tied together to prevent the upper ones from slipping forward on the head, and the lower downwards on the neck. This bandage may be used for the head by placing the centre piece on the top, tying the hinder ends under the chin, and the forward ones at the back of the neck.

The Many-tailed Bandage or Scultetus is shown in Fig. 350. It is used to apply to a limb when, owing to injury, it is extremely undesirable to disturb the limb by lifting, &c., to the extent that is necessary when the roller bandage is passed time after time round the limb. It may be made of an ordinary roller,

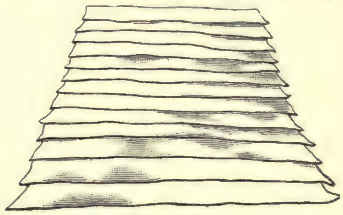

Fig. 350.—The Many-tailed Bandage.

which is cut into lengths sufficient to encircle the limb and leave 3 or 4 inches for overlapping. Thus, suppose it were wanted for the thigh. The measurement of the thigh at the knee, at the middle, and at the top would be taken. Then strips would be taken of those lengths, with an addition of 3 or 4 inches in each case. Other strips would be cut in lengths showing a gradual increase from the one near the knee to the one for the top of the thigh. Of such strips eighteen or more would be required. They are then arranged on a towel. Lay the strip that will encircle the *top* of the thigh down near one end of the towel. Lower down lay the next strip and make it cover the first to a third of its breadth; lay the next one in the same way to cover the lower border of the second, and so on till all the strips are in position one overlapping the other to the appropriate amount. A strip may then be placed right down the centre and fastened to each strip by a stitch, but this is not necessary. The towel may then be folded from one side to another and laid aside till required. When the bandage is to be applied the limb is gently raised, the towel, unfolded with the strips all in position, is slipped under it and properly placed. Then all that is necessary is to begin with the *lowest* strip, bring an end up on each side and overlap them, the ends of the second strip are similarly overlapped, and so on *up the limb;* and when the last strip is folded over and secured, one

ought not to be able to tell the difference between this bandage and one put on in the ordinary way.

Bandages for the Head.—There are several ways of bandaging the head according to the object in view.

The Capelline Bandage (Fig. 351) is used to secure dressings. It requires a two-headed roller, that is, a long bandage 12 yards long and 2 inches wide, rolled up from each end till the

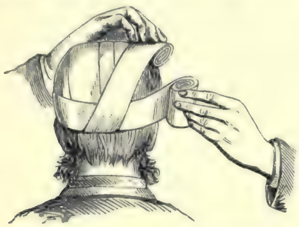

Fig. 351.—The Capelline Bandage.

two rolls meet. The middle of the roller is laid against the forehead, and one end is passed round one side of the head, the other round the other side till they meet low down at the back. Here they are crossed. One end is then continued on its way round the head, the other end is carried up over the top of the head and down to the forehead. Here the roller travelling round the head passes over it to fix it down. It is then turned up and crossed over the head again, this time overlapping one side of the first turn over the head (Fig. 351), and when it reaches the back the travelling roller passes over it to fix it down again. For the third time it is brought over the head, this time overlapping the other side of the middle fold. So on the process is repeated, one roller being carried continuously round the head, the other passing backwards and forwards, now on one side of the middle line, now on the other, till the whole head is covered as shown on Fig. 352.

Fig. 352.—The Capelline Bandage Complete.

The Twisted or Knotted Head Bandage is employed when it is necessary to exert pressure on the artery at the temple to stop bleeding. A two-headed roller, 8 yards long, 2 inches wide, is used. The middle of the roller is laid on the injured temple, and under it is placed a cork inclosed in a double thickness of lint. One end of the bandage is carried round the front just above the eyebrows, the other backwards low down, till they meet at the opposite temple. Here they cross one another. When they meet over the injured part a twist is made exactly over the injury, and one end is carried under the chin, up the other side of the head, and on to the top of the head, where it crosses the other end which has been carried upwards. Both are carried on till they again meet over the injury, where a second twist is made, and the ends then carried round the head and fastened. One twist should exactly lie over the previous one. This may be done in a simpler way with an ordinary roller. Unroll about a foot of the bandage; hold it in one hand near the seat of injury, carry the roller round the head, and when it comes back to the wound give a firm twist with the loose end; then carry the roller under the chin, up the opposite side and over the top of the head, and when the wound is reached repeat the twist. Finally, carry the roller horizontally round the head again, and fix it by knotting the two ends. (See Fig. 353.)

Fig. 353.—Twisted Bandage for Head.

A Simple Bandage to keep a dressing in position on the head needs only an ordinary roller. It is carried horizontally round the head above the eyebrows and low down behind, and, when it is once round, the turn is fastened by a pin. The bandage is then passed obliquely over the head across the dressing, and when it gets down to the horizontal turn it is passed once completely round, thus fixing the oblique portion. A second oblique turn is now made over the head, overlapping the former, and so on. A still simpler method, however, is to use the triangular bandage or a folded handkerchief to make the shawl cap.

The Shawl Cap is a very light bandage for retaining dressings. Fold a handkerchief into a triangular shape, as a shawl is commonly folded. Let the straight edge be applied to the forehead above the eyebrows, and the point lie over the back of the head. Carry the two ends to the back, cross them over the point, and then bring them round to the front and tie them there. Then turn the point up over the crossed ends and fix it with a pin. (See figures in Plate XV.)

Starch Bandages are roller bandages of loose texture, such as crinoline cloth or muslin, which are loaded with a thick starch paste, just before being applied. A thick paste of boiled starch is made, and while it is still hot the roller bandage is unrolled and passed through it, being loosely rolled up as it becomes charged with the starch. Before applying such a bandage to any part of the body, an ordinary roller ought to be put on, and any projecting parts protected with cotton-wool. Then, when the starch bandage is being applied, additional stiffness is secured by rubbing over the turns some of the starch paste. When the whole is complete it is covered in by an ordinary roller. The person on whom the bandage has been put must maintain the position of the bandaged part undisturbed for many hours, to allow the bandage to harden without change. Indeed it is a day or two before such a bandage would be sufficiently hard to enable movement to be made without risk of disturbance. This is the disadvantage of the starch, and herein lies the superiority of the plaster of Paris bandage. Such a bandage might be employed to put up a fractured limb, to keep joints at rest, and to exert continuous pressure over swollen parts.

The Plaster of Paris Bandage is much more useful than the starch bandage. Well-dried plaster of Paris is used. If the plaster has been kept in badly-closed tins, so that it has become damp, it may be dried in an oven with a heat not exceeding 200° or 260° Fahr.; a greater heat would destroy its setting power. A muslin or crinoline cloth roller of coarse open texture is used. As it is gradually unrolled on a table, the dry plaster of Paris is rubbed into it by one person, while another rolls it up loosely, keeping plenty of the powder between the turns. The limb or part of the body to be encased is meanwhile covered in by an ordinary roller, or by a flannel bandage, cotton-wool being placed over any parts requiring protection, and in the case of the foot between the toes. A minute or so before it is to be used, the loaded roller is placed on end in a vessel of water. There should be sufficient water to cover it. It is then applied to the limb or part prepared for it, in the case of a limb being begun at the extremity. The application must be made quickly, the plaster sets so quickly, but at the same time it should be uniform and neat. It is usual to increase the stiffening by making a thick cream with plaster and water, with which the turns of the bandage are smeared as they are rolled round the limb. Usually a couple of bandages 6 yards long are sufficient to produce the requisite degree of stiffness. After the plaster bandages have been applied, a dry roller is put on; the patient remains still, and within half an hour the whole bandage is quite firm. In the case of the leg, the person would be kept still, however, for several hours before movement was permitted, in order to secure perfect hardness and dryness of the plaster. Such bandages are quite commonly applied for fractured limbs, if they can be put on quickly after the accident and before swelling begins. The great advantage of such a method is that within a short time after the application has been made the patient can be transported for any distance without risk of displacement of the ends of the broken bone. They are also very useful for joints which it is desired to keep at rest, in order to permit of the removal of swelling, dropsy, &c. For instance, in the case of swelling of the knee-joint as the result of inflammation or sprain, &c., it is often possible by the use of a plaster bandage to permit the person to go about who, but for the support of the bandage, would be confined to bed or a couch. The employment of this bandage for spinal disease has been illustrated on p. 28.

The Triangular Bandage is of all others the bandage made use of for rendering temporary aid in cases of accident, and is the bandage now familiar almost to everyone, through the training in "First Aid to the Injured" afforded by ambulance associations. It was introduced by the distinguished German surgeon Professor Esmarch, as a means of applying a first dressing on the battle-field. Esmarch's bandages, and

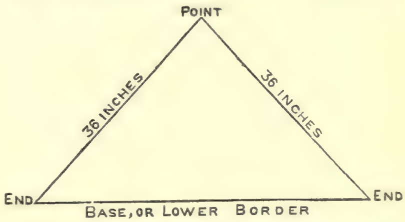

Fig. 354.—The Triangular Bandage.

the bandages supplied by ambulance associations, usually have stamped upon them illustrations of the various uses to which they may be put in securing splints and dressings, in applying pressure to prevent bleeding, in acting as slings to give support to injured arms, and so on. The bandage is made of a square yard of calico or linen halved. Each of the two halves is a triangular bandage, having, of course, two sides 36 inches in length, meeting at the point of the triangle,

and a base considerably longer, fully 50 inches (Fig. 354). The application of this bandage for the securing of temporary splints in cases of fracture is described in the third section, and its use for controlling bleeding from injuries is illustrated in the next section; but a few of its other uses will be pointed out here.

The Triangular Bandage as a Sling is illustrated in Plate XV. The bandage is laid, unfolded, across the body, one end passing over the shoulder opposite to the injured arm, the other end hanging down, and the point projecting out beyond the elbow of the injured arm. The arm to be bandaged is bent at the elbow, and carried over the chest, the hand being held higher than the elbow. The hanging end of the bandage is now brought up over the forearm and round the root of the neck on the same side, being tied with the end which passed over the opposite shoulder. The point is then brought neatly round the elbow and secured with a pin in front. (See Plate XV.) Such a bandage, when properly applied, carries the weight of the arm and relieves the shoulder. Sometimes only the hand and wrist are supported, the weight about the elbow being unsupported, as in cases of broken upper arm-bone, when the weight is needed to keep the upper arm on the stretch and prevent the broken ends of bone from riding on one another. In such a case the **small arm sling** is applied. (See Plate XV.) This is done by folding the bandage into a cravat-form, by folding the point down to the base and folding again so that a proper breadth is secured. The two ends are then passed round the two sides of the neck and secured as shown in the plate.

The Triangular Bandage for the Hand.—Spread out the bandage fully; lay the hand flat upon it palm downwards, the wrist resting on the base or lower border, the fingers directed to the point. Bring the point of the bandage over the fingers and back of the hand and let it pass over the wrist up the back of the forearm. Bring the two ends round the wrist, securing the point, cross them and carry them round to the front of the wrist, cross them again, bringing them to the back of the wrist, and tie them there. The point may be folded down over the crossing of the ends, on to the back of the hand, and fixed there with a safety-pin. The hand bandaged is shown in Plate XV.

The Triangular Bandage for the Arm.—Fold the triangular bandage into a broad bandage by folding the point down to the base or lower border, and then folding into two. Place the centre of this over the part to be covered, carry the ends round the arm, cross them, and carry them back again; let them be crossed again and carried round once more to the opposite side, where they are tied.

The Triangular Bandage for the Elbow.—Lay the centre of the bandage over the back of the elbow-joint, its lower border or base crossing the back of the forearm, its point passing up the back of the upper arm. Take the ends round in front, cross them, carry them to the back above the joint, and tie them there. Then fold down the point over the ends and secure it with a pin.

The Triangular Bandage for the Shoulder.—Spread the bandage out over the injured shoulder, its centre over the point of the shoulder, its point passing up the neck, its base or lower border resting over the middle of the upper arm. Pass the ends round the arm, cross them, bring them to the front and tie them there. Take a second triangular bandage, fold it into the small arm sling, and with it support the forearm. Let this sling pass over the part of the shoulder bandage that reaches up to the neck. Fold down the point of the shoulder bandage over the sling, and secure it with a safety-pin. This arrangement is shown in Plate XV.

Another way of bandaging the shoulder, when it is unnecessary to support the forearm, is to fold a second triangular bandage into a narrow bandage and carry it over the injured shoulder across the body and under the opposite arm-pit, the ends being pinned at the back and the front. The point of the shoulder bandage is then folded over this and pinned as in the former case.

A *single* triangular bandage may also be used to secure dressings, hot fomentations, poultices on an injured shoulder, in the following way. Let the centre of the fully unfolded bandage be placed over the shoulder as before, its point passing up the neck; carry the ends round the arm to the arm-pit, cross them there, and then take one end up in front of the shoulder, another up behind, and tie them, or pin them, over the top of the shoulder, then fold down the point over the ends and fasten it.

The Triangular Bandage for the Chest.—Spread the bandage out over the injured side, with its centre over that side; carry the point over the shoulder of that side, carry the two ends round the waist, knotting them there, one end being left long. To this end tie the point which has passed over the shoulder (Figs. 355, 356). The knots should be so placed to one side

that they are not pressed upon when the patient lies down.

The Triangular Bandage for the Back is applied similarly to that for the chest, only the

Fig. 355.—Front View.

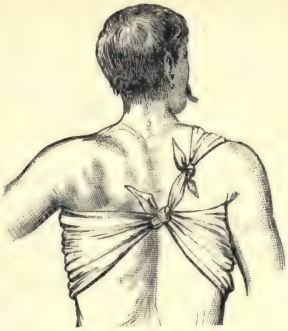

Fig. 356.—Back View

The Triangular Bandage applied to the Chest.

bandage is spread out over the back, the point passing over one shoulder and the ends round the waist to be knotted in front. This is an excellent method of fastening on poultices, dressings, &c. Where knots are undesirable the ends should be secured by safety-pins.

The Triangular Bandage for the Foot.—Spread out the bandage and lay the foot flat on it so that the end of the big toe is about the centre, the toes directed towards the point. Fold the point down over the toes and back of the foot, letting it pass up the front of the ankle. Bring the ends over the back of the foot, cross them, carry them round to the back of the ankle, cross them there, and bring them round to the front of the ankle, where they are tied. The point may then be folded down over the ends.

The Triangular Bandage for the Knee is similar to that for the elbow. The centre of the bandage is placed over the joint, the point directed upwards. The ends are carried behind, crossed; brought round to the front and tied, and the point is folded down over the knot and pinned.

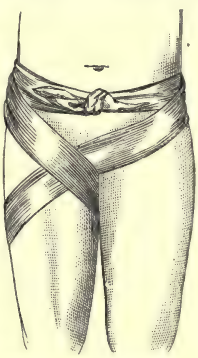

Fig. 357.—The Triangular Bandage applied to the Groin.

The Triangular Bandage applied to the Groin.—The triangular bandage may be used to fix dressings on the groin by folding it into a narrow bandage. To do this spread out the bandage, bring the point down to the middle of the base, then fold into three. Place the middle of this narrow bandage close up between the two legs, carry one end up in front along the groin, carry the other end up behind along the fold of the buttocks, cross them on the outside of the hip, and then carry the ends round the haunches, to tie them on the opposite side, or if the bandage be long enough continue the ends to the front and tie them there (Fig. 357).

The buttocks require two triangular bandages. One is folded into a narrow bandage and tied right round the body as a belt, always low enough to be over the haunch-bones. A second bandage is spread out so that its point passes up on the outer side of the buttock to be covered. The point is passed up under the belt and then folded down over it, to be pinned there. The middle of the base or lower border of the bandage should reach down below the lower edge of the fold of the buttocks. The ends are carried round, one over the front of the thigh, the other behind, and are tied or pinned (Fig. 358).

Fig. 358.—Triangular Bandage applied to the Buttocks.

The Triangular Bandage for the Head is applied in the form of the shawl cap, as described on p. 960, and illustrated in Plate XV.

The Knotting of Bandages.—The knot which is commonly made is familiarly called the **granny knot**. The direction which the

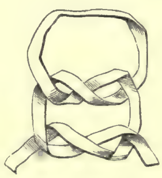

Fig. 359.—Granny Knot.

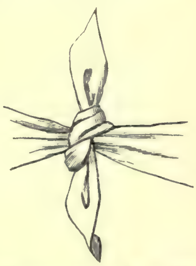

Fig. 360.—Granny Knot tight.

ends take is shown in Fig. 359, and the appearance of the knot when drawn tight on a bandage is illustrated in Fig. 360; the ends

set *across* the direction of the bandage. This knot should never be used for surgical purposes. The thread, tape, or bandage so tied is seldom secure, and always liable to slip. It is in surgery usually of the utmost consequence that the possibility of slipping should be entirely discounted, especially when the firmness of dressings over a wound or the stoppage of bleeding is dependent upon the knot being secure. In all such cases the **reef-knot** should be employed (Fig. 361). It will be noticed that in both cases the first turn is the same. When this has been made, if the loose end opposite the person's right hand be carried across and held in the left hand while the other end is taken first *under* it and then over it, the ends will be in the position shown in Fig. 361. In the case of the granny knot the second end is taken *over* the first and then under it. When the ends of a bandage are tied in a reef-knot, and the knot pulled tight, the appearance of the knot is as shown

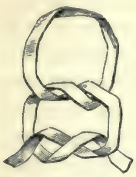

Fig. 361.—Reef-knot.

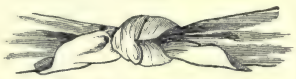

Fig. 362.—Reef-knot tight.

in Fig. 362; the ends set *in line with* the direction of the bandage.

The **clove-hitch** is used for fastening a bandage or towel round a limb in order to give good hold for a firm pull. Fig. 363 shows how it is made. The bandage is caused to make two turns or bends on itself, as shown. The second bend, that to the right in the figure, is then placed behind the first, and through the space formed by the opposite halves of the two, and marked + in the figure, the limb is placed. Fig. 364 shows the hand passed through and the ends of the clove-hitch hanging from the wrist. The two ends, being taken hold of, afford an excellent means by which the arm may be strongly pulled on. The more strongly one pulls the tighter does the noose become, and there is no possibility of it slipping, while it may be unloosed, if needful, in a moment. In a case of dislocation at the shoulder-joint, for example, the clove-hitch

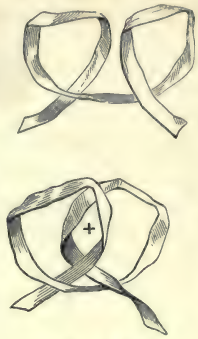

Fig. 363.—Clove-hitch.

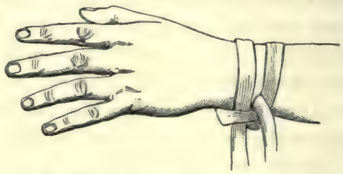

Fig. 364.—Clove-hitch applied to Wrist.

would be applied round above the elbow-joint, and thus the lower end of the dislocated bone would be directly pulled on in the effort to reduce the displacement.

SECTION II.

THE TREATMENT OF WOUNDS AND BRUISES. THE ARREST OF BLEEDING. POISONED WOUNDS, SNAKE BITES, AND INSECT STINGS.

Wounds and Bruises and their Treatment.

Varieties of Wounds:
Incised, Punctured, Lacerated, and Contused Wounds.
The Repair of Wounds:
Healing by Immediate Union;
Healing by First Intention—Scar or Cicatrix;
Healing by Second Intention or Granulation—Healthy Pus.
The General Treatment of Wounds:
The Stoppage of Bleeding;
Cleaning the Wound;
The Closing of the Wound—The Use of Strapping and Sutures;
The Protection of the Wound—Dressings and Bandaging.
The Re-dressing of Wounds.
The Treatment of Incised or Clean-cut Wounds.
The Treatment of Punctured, Bruised, and Lacerated Wounds.
The Treatment of Wounds of the Scalp.
The Treatment of Bruises or Contusions—Ecchymosis—How to Treat a Black Eye.

The Arrest of Bleeding.

The Distinction between Bleeding from an Artery, a Vein, and Capillary Vessels.
The Methods of Stopping Bleeding:
Elevation of the Wounded Part;
The Application of Cold and Astringent Substances—Styptics;
The Application of Pressure;
To Arrest Capillary Bleeding;
To Arrest Bleeding from a Vein;
To Arrest Arterial Bleeding—Methods of arresting bleeding from the arm and hand, foot and leg, head and neck, nose;
Tourniquets and how to apply them to stop bleeding;
Artery Pressure or Catch Forceps.

Poisoned Wounds; Insect Stings; Snake Bites; and other Kinds of Poisoned Wounds.

Poisoned Wounds and their Treatment.
Stings and Bites of Insects and other Animals:
Bees' and Wasps' Sting and its Treatment;
The Mosquito Bite;
The Chigoe or Jigger;
Ticks; Bed-bugs; Spiders—The Tarantula;
The Scorpion and Centipede;
The Guinea-worm.
Snake Bites:
Non-poisonous Snakes—The Common Snake, the Black Snake, the Anaconda, Pythons, and Boa.
Venomous Snakes—The Viper and Rattlesnake, the Water Viper or Moccasin, the Copper-head and Cotton-mouth, the Harlequin-snake, the Jararaca, the Tiger-snake and Death Adder, the Horned Snake and Puff Adder, the Asp, the Cobra, Bungarus, Russell's Viper and Ophiophagus Elaps.
The Treatment of Snake-bite.
The Poison of Venereal Disease:
Gonorrhœa, Bubo, &c.

WOUNDS AND BRUISES AND THEIR TREATMENT.

Varieties of Wounds.—Wounds are commonly divided into four classes: (1) **incised wounds,** inflicted by sharp instruments, so that the wound is clean cut; (2) **punctured wounds,** wounds caused by narrow instruments being forced into the body, including stabs, pricks,

&c.; (3) **lacerated wounds,** which are of the nature of tears; and (4) **contused wounds,** which are caused by falls or blunt instruments, and in which the parts about the wound are bruised. These distinctions are of importance even from a popular point of view. There are, comparatively speaking, few people who are unfortunate enough to get a bone broken, but almost no one, if any one, escapes a wound of one kind or another. Everyone ought to know, in a general way, how to treat the ordinary kind of wound, of which every household has more or less experience, and a knowledge of the distinctions between the different kinds of wounds enables one to perceive very easily the appropriate means of dealing with each as it arises. In the simple clean-cut wound, for example, there is practically no destruction, no death of parts. Supposing the instrument to have been clean and the wound clean, setting aside for the moment the question of bleeding, there is little needed, it is plain, but the accurate bringing together of the divided parts to secure the closure and healing of the wound. On the other hand, in the case of the contused wounds, or wounds accompanied by bruising, there is destruction more or less severe and more or less extensive of some of the wounded tissue. The vitality of the parts has been lowered, their power of repair seriously diminished, and of some portions of them completely abolished. It is evident that the attempt to close such a wound, as one would a clean-cut wound, is doomed to failure, for the parts that have been destroyed, however small, must come away before healing can occur. When the bruising has not been severe enough actually to destroy any of the tissue, it may be that by appropriate methods, by careful nursing of the wound, so to speak, the diminished vitality may gradually be restored to full activity and all the tissue saved. But to adopt the methods proper for keeping close together the cut surfaces of the clean-cut wound might be to ensure the death of the parts in a bruised wound. A torn wound is in something of the same position. If the parts have not been pressed upon, as in the bruise, they have been violently torn apart, and the strain upon the tissue must have seriously lowered its vitality and power of repair. Then the punctured wound will partake more or less of the character of the clean-cut wound, if it has been inflicted by a sharp-pointed and sharp-edged instrument, or of a bruised wound if the instrument has been blunt-pointed, or, while sharp in the point, is thick and blunt beyond it, as, for example, a steel for sharpening knives; or the punctured wound may be also of the nature of a tear. But one special point to be remembered about it, whatever its character, is that it is deep out of all proportion to the extent of wound shown on the surface, that if the instrument were dirty, some of the dirt may be lodged in the depth of the wound, beyond the reach of sight, or some fragment of clothing or other material may have been carried in with the point of the instrument, or, for that matter, some portion of the instrument which did the damage may have broken off in the depth of the wound and be lying there.

Now many people who read these sentences will be inclined to say, "Oh, well, really, these are fine points for a surgeon to consider, which the ordinary man or woman cannot be expected to take into account." But this is not, in any sense, true. They are most important points, but they are not "fine points" nor "difficult points." They need the exercise of nothing more, or little more, than ordinary common sense. So long as cut fingers, and broken knees, and bumped heads are the common incidents of a household—so long as wounds and bruises are the everyday occurrences of a workshop—so long as every mother thinks that she is quite fit to attend to the ordinary run of these things herself, and every workman that he can "doctor" any ordinary small affair himself, so long should every man and woman think it necessary to look at the simple common sense of the matter, and be ready to apply it when necessary. Therefore let us look for a minute at the two ways of regarding even the minor wounds and accidents which everyone thinks he can treat "just as well as the doctor." The one way is to regard its mere size, and if it does not look big, and there is nothing terrifying in its aspect, and no bleeding worth talking about, to cover it up with a rag or stick a piece of plaster on it, and expect it to heal without further trouble. And of course, in nine cases out of ten they do heal, because nature is fit for the most of the demands made upon her reparative powers. But perhaps the tenth case goes wrong, and, as likely as not, the injury seemed at first of the most trivial kind. Nevertheless, owing to the want of observing a little common sense, and after many days, the doctor is, perforce, appealed to, because the slight cut, or the small bruise, or the prick that was hardly worth talking of, has become a large, deep, foul sore, which refuses to heal, and gives much pain and general disturbance. Now what we have

called the common-sense way of looking at even a trifling injury is followed, when the person asks himself the question, What kind of a wound is it? is it a clean-cut wound which should heal easily, or is there much damage to the parts which may cause it to heal with greater difficulty? secondly, when the person asks the question, What did it? the answer to which will probably indicate whether any foreign material has been carried into the wound, likely to lead to an interference with its quick healing; and thirdly, when the person gets, if possible, the object which caused the wound, still further to settle the second point, and to make certain that, if it was material likely to break, no part has been left in the wound. It does not need much, if any, special skill to determine these points, and when they are determined anyone will be in the position to decide with tolerable accuracy whether the wound is as trifling as it looks, and whether simple and unskilled treatment will be sufficient. For it must never be forgotten that the smallest possible wound may occasion the greatest possible trouble, if by it there gain entrance to the body any foul or putrefying material capable of propagating itself in the tissues, and that tissues of lower vitality, and consequently diminished resisting power, will offer to it a most suitable lodgment.

If, then, one remembers the four different kinds of wounds, little difficulty will be experienced in deciding, regarding the ordinary run of simple injuries, which of them are the more serious, and what are the special things to be attended to in dealing with them.

The Repair of Wounds.—The clean-cut wounds show the simplest and most rapid method of repair when they heal by what is called **immediate union.** In this case the surfaces of the wound are brought accurately together throughout their whole extent; they adhere closely, and after the lapse of a few days they have become reunited, and are continuous, the circulation being completely re-established, *no scar being left* to indicate where the wound was. This is a mode of healing that does not very often occur, and can take place only under the most favourable circumstances. It is evident that it cannot occur unless every portion of the divided parts, and not the *edges* of the wound only, are accurately and firmly replaced in their original situation. This cannot be done if streaks and clots of blood are allowed to remain in the wound, or if bleeding goes on after the wound has been closed, or if particles of dirt are left in it; nor can it occur if matter forms; nor is it at all likely to take place if any time has elapsed since the wound was produced, so that the two surfaces of the wound have become coated with a film of coagulated material. In all other methods of repair new material is formed to fill up the breach which the wound has caused. This new material is not produced from the blood clot which may fill the wound. It seems to be produced from two sources. In describing the structure of the blood, on p. 213, the white cells of the blood, or white blood corpuscles, or leucocytes, have been spoken of, and it has been explained on p. 214 how these cells are capable of passing through the walls of the fine blood-vessels and wandering through the tissues. Now if a small piece of the material which is filling up a healing wound be examined under the microscope it is found to consist of a mass of such white cells, and the belief is that soon after the wound has been produced white cells from the neighbouring vessels find their way to the seat of injury, and there multiply in enormous numbers, affording thus the material for repair. This is not a mere fancy nor bit of imagination; the process can be witnessed going on under the microscope. The passing of the white blood corpuscles from the fine capillary vessels may be watched in the web of a frog's foot, viewed under the microscope, if the surface of the web be irritated in

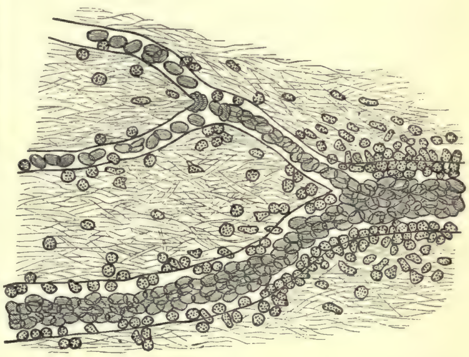

Fig. 365.—The appearance under the microscope of a minute piece of fine tissue which has been irritated. A blood-vessel is shown branching. The red corpuscles are seen streaming down the centre of the vessel, the white corpuscles are rolling along the walls of the vessel, adhering to them, and passing out of the vessel in great numbers, and finding their way in the direction of the seat of injury.

some way. The appearance under the microscope is shown in Fig. 365. Every tissue, skin, muscle, nerve, bone, &c., contains a certain amount of connective tissue (see p. 16). One of the elements of connective tissue is cells, which, in the opinion of some, are capable of

multiplication, so that some of the new growth formed to fill up a wound may be derived from the cells of the connective tissue of the part. Suppose then a clean-cut wound, and the edges brought together. The two cut surfaces are not absolutely united, a fine probe could readily be insinuated between them, just after they have been brought together. But in twenty-four hours this is no longer so, the fine gap is filled up and the edges of the wound are glued together. Of course a little violence would still separate them; but the difference between the state of the wound now and its condition twenty-four hours before is marked. What is the cause of this? The gap is filled up by cells held together by material which has oozed from the blood-vessels, of a fibrinous nature, which "sets," so to speak, and thus glues both sides of the wound together with the cells into one closely coherent mass. The cells undergo rapid change of form; from round cells they become spindle-shaped, and in the course of a few more days the wound is united by a wedge of new tissue of a fibrous character, which condenses and becomes firmer, and into which an extension of blood-vessels takes place from surrounding parts, so that by and by the position of the wound is only indicated by a fine white line, or scar, or **cicatrix**, the edge of the new slice of tissue which nature has introduced to unite the separated surfaces. A wound which unites in this way is said to heal "**by first intention.**" This is the kind of union one seeks to bring about; there is no loss of substance, no matter is produced, and there is no interruption to the healing process. For such union it is necessary that there be no blood left in the wound, or dirt of any kind, since either would interfere with the healing process by leading to the formation of matter which would require to be expelled. Then healing by first intention cannot occur in a wound accompanied to any extent by bruising, for particles of the tissue are in such a case destroyed, and will be sooner or later separated from the living healthy tissue.

In wounds where there is any loss of substance, any destruction of particles of the tissue, healing takes place by what is called **granulation**, or by **second intention.** In the case of a wound on the surface, say a bruised wound, there is a discharge from the surface, a thin yellowish-red discharge, consisting partly of fluid oozing from the wound and partly of the dead particles of tissue. In the course of a few days the wound has become an open sore, with a more or less even surface considerably below the level of the skin. After all particles of dead tissue have been removed the surface of the wound should be uniformly clean and red. If it be carefully examined it will be seen that the surface is not glazed and smooth, but is covered all over with fine red granules projecting from the surface. These are called **granulations.** They are formed by masses of the round cells already spoken of, and fine loops of blood-vessels project up from the sound tissue below into the granulations. They are, in a healthy wound, fairly firm, but any rough handling will make them bleed. They grow rapidly, coalescing with their neighbours, and as this goes on the wound gradually becomes shallower, gets filled up, and approaches the level of the surface. The material thus formed is really the same as that which united the opposed surfaces of the closed wound. During this process matter is continually being separated from the surface, of a creamy thickness and pure yellow, and without smell, if the wound has been kept clean. This matter is called **pus**, healthy pus, and if it be examined under the microscope it is seen to consist of round cells; in fact of cells similar to the wandering cells spoken of, and which come from rapidly-multiplying cells of the granulations. When the gap caused by the wound has been filled up and the granulations reach the level of the skin, the surrounding skin begins to advance inwards. A pink border surrounding the wound indicates the activity of the circulation going on to aid growth, the pink border thinning away towards the wound. Day by day the size of the wound is seen to be lessened, until it is wholly covered by a scar, formation of matter having ceased. In the deep parts of the new tissue condensing changes occur, which also extend to the surface, and this shrinkage goes on for a prolonged period till the size of the scar or cicatrix is ultimately very much smaller than that of the original wound.

When the granulations receive too great a supply of blood, they become excessively large and flabby, and soft, not firm as they should be. They are said to be exuberant. In such circumstances they sprout beyond the level of the skin, and are popularly called "proud flesh." It is common to reduce them by the use of caustic. This is a mistake. Firm pressure with a pad and bandage will usually restrain them sufficiently to enable healing to go on to a satisfactory termination.

When healing takes place under a scab it very much resembles that which occurs in the healing by first intention. But, owing to the

presence of irritating material, matter may form under the scab, and its confinement might lead to extensive destruction of parts and the production of a deep sore. This, however, would be indicated by pain, inflammation, and a soft boggy feeling of the part. When, however, the wound and its scab are firm and dry, and there is little redness or tenderness, one may be assured that the healing process is going on satisfactorily, and when the wound is finally closed the scab will become readily detached. The scab is, in short, nature's method of closing the wound to prevent the entrance of disturbing elements from the outside, and of protecting the part till the breach has been repaired.

Now it must not be supposed that it is only in exposed wounds, in wounds on the surface of the body, that such methods of repair are found. Injuries in the deep parts are repaired in precisely similar ways. Bone is repaired in a similar way: the new tissue, which in the skin takes on the resemblance to skin, in bone comes in time to resemble bone, knitting its broken ends firmly together. Muscle is repaired in a similar way, so also is nerve. If a divided nerve be accurately united the new tissue formed at the place of union will in time take on the form of nerve tissue, and the function of the nerve may be restored.

The General Treatment of Wounds.—It will be clear from what has been said that the treatment of wounds will vary to some extent with the nature of the wound. While that is so, there are certain general rules to be followed with any or every wound. Let us see first of all what these are, and then we can consider what changes are required to meet the different kinds of wounds. The rules are these:—

I. Stop bleeding.
II. Cleanse the wound and remove all dirt and other foreign material.
III. Restore the parts, as nearly as possible, to their proper positions, diminishing gaping as much as possible.
IV. Secure complete rest to the part, and protect it from outside influences, but take care to prevent the accumulation on or in the wound of any discharge.

I. As to the arrest of bleeding, the proper methods of doing so will be considered later in this section. A very large number of the ordinary wounds, however, give little trouble in this respect. It is only when an artery has been cut, or a vein of some size, that bleeding is troublesome enough to tax the resources of the layman. Raising the part, the use of cold water, pressing on the wound itself with a piece of clean lint, will usually be sufficient to stop the welling up of blood from the ordinary wound. One thing must not be done: cloth after cloth, handkerchief after handkerchief, must not be piled on the wound, and then the whole part enveloped in some ample dressing. If an artery or large vein has been wounded, it is highly improbable that the bleeding will thereby be made to cease. It will only continue, *without being seen*, till the whole mass of covering has been soaked through. No one must delude himself with the belief that bleeding is stopped *because it is hid*. This is akin to the fatal policy of the ostrich, which hides its head in the sand, in the delusion that the hunter will not see it because it does not see him. Nor is it advisable to pour on the wound substances like friars' balsam, or steel drops, or other discolouring and sticky substances to arrest the bleeding. No attempt should be made to bring the surfaces of the wound together or to dress it till bleeding has ceased. Often when no large vessel is wounded there is a very considerable flow of blood from the fine capillary vessels, which does not readily stcp. For this the use of an iodine lotion is recommended, 20 drops tincture of iodine in an ounce of warm water, or, roughly, as many drops of the tincture in a basin of warm water as will make the water of a light sherry colour. A sponge, or, preferably, a piece of clean lint wrung out of this lotion and pressed on the wound for a minute will usually be sufficient. It is besides a useful lotion for cleaning the wound.

II. The cleaning of the wound and the arrest of bleeding will often go together. Even though the cleansing of the wound starts the bleeding afresh for a little, it must be done, since to permit a mass of blood clot, dirt, &c., to remain in and around the wound is only to encourage decomposition and the production of a foul-smelling sore and to delay the healing process. But the cleaning process should not be roughly done. A gentle stream of water, tepid or cold, is caused to play on and about the wound; and gradually clots and foreign material will be washed away. Small pieces of surgeon's lint may be used, well wetted, gently to wipe the wound, and assist in the removal of clots, &c. The water should contain some antiseptic material, if it is at hand, such as carbolic acid, 1 ounce to 2 pints of water, or the iodine lotion already mentioned. When the wound and surrounding parts are thoroughly clean, it should be carefully examined

to see that no foreign material lurks in its corners or is embedded somewhere in it. As already mentioned a knowledge of what caused the wound will help in determining whether any splinter of material is likely to be buried in it. If so, it must be searched for and removed, otherwise suppuration will ensue, and the wound will refuse to close till it has been removed.

III. The restoration of separated parts to their original position is easily accomplished in clean-cut wounds, and is the proper thing to do, since it promotes their speedy union. But in torn and bruised wounds accurate replacement is needless, since some of the tissue is certain to break down and be separated, either in pieces, which are called **sloughs,** or in the form of discharge. Still the chance of their reuniting should be taken advantage of, though not to the same extent as in the clean-cut wounds, and care must be taken to provide for the escape of any discharge or separated particles. The surfaces of the clean-cut wound are brought together either by strips of adhesive plaster, by sutures, or stitches. It must not be forgotten, however, that the edges, the surface, of the clean-cut wound may be brought together and the deep parts may gape. Fluid and blood may, therefore, ooze between the deep parts of the wound, separating them farther, while the external edges are uniting. Thus a collection of matter may form in the depth of the wound, bursting open the united edges sooner or later, and causing pain and swelling before that occurs. In every clean-cut wound of any depth, therefore, surgeons as a rule try to unite the divided surfaces by the passing of sutures or stitches from one side of the wound, through its depth, to the other side, and further aid in keeping the parts together by carefully-adjusted pads at a little distance from each side of the wound. In shallow wounds strips of plaster may do all that is necessary. But in exposed parts, where it is desirable to have as little scar as possible, as on the face, even shallow wounds are stitched together. The sutures are usually of silver wire, or of catgut or silkworm gut, usually soaked in carbolized oil, appropriate needles being employed. In shallow wounds black silk thread, well waxed with bees'-wax, introduced by fine sewing needles—No. 9—suit excellently. The use of carbolized catgut or silkworm gut is now very extensive in surgery, because it does not require removal after the wound has healed. The part buried in the tissues becomes gradually softened and absorbed, and the external ends then drop away. The ordinary adhesive strapping, or lead plaster, is in common use for closing a clean-cut wound. It should be cut in strips of about a quarter of an inch in breadth and of sufficient length to extend a considerable distance on each side of the wound in order to have a sufficient surface of support. The plaster is warmed all over its surface by heating before a fire or over a gas flame, and is fixed on one side of the wound. Then while the finger and thumb of the left hand keep the edges of the wound accurately together, the right hand carries the strip over to the other side. The plaster is smoothed down close over the skin and held for a few seconds till it has secured a firm hold. If the wound or skin be wet, the plaster will of course not adhere at all. A method of applying the strips to avoid "cockling" is shown in Fig. 366. Two strips are used,

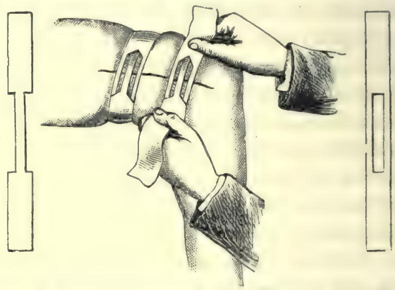

Fig. 366.—A Method of applying Strips of Plaster to close a Wound.

cut as shown in the figure; one is applied on one side of the wound, and the other on the other side. The end of one strip is then passed through the slit in the centre of the other, and then an even pull on both ends accurately closes the wound. The strapping should never completely cover the wound. Intervals should be left between each strip, and the corners of the wound should not be strapped, that an opening may be left for the escape of any oozed fluid.

It has been said that it is undesirable to attempt to close bruised or lacerated wounds, since the death of some part of the tissue is almost certain. As a rule, that is to say, sutures or strapping are not employed to bring the separated surfaces together, though parts are replaced, after being cleansed, as nearly as possible in their proper positions. In the case of punctured wounds, however, the external opening of the wound is kept open, instead of its union being promoted, in order to ensure the escape of any discharge or oozing of blood, &c., from the depth of the wound. It is not till the lapse of a few days, when all risk has passed away, that the opening is allowed to close.

IV. The protection of the wound from dis-

turbances of various kinds is one of the chief means of promoting its healing. One of the most important ways of securing this is by rest, complete rest of the part involved. Suppose a cut extends across the wrist, nothing could be more hurtful, or could more seriously delay healing, than the use of the hand in any occupation whatever. Many people think if the part has had some dressing applied and is bandaged, it should be sufficiently supported, and that they ought to be able to go about their ordinary duties. If it does not unite rapidly, and if it shows signs of inflammatory action along the edges, they are strongly disposed to blame the surgeon for not having applied the appropriate dressing, ignoring the fact that they are not giving the opportunity for natural recovery. If, therefore, any part of the hand or arm has been wounded, it should be carried in a sling. If the wound is near a joint, a splint will probably be applied to prevent motion of the joint. In every wound of the fingers, of any extent, this is a necessity. If the wound is on the foot or leg it is proper for the patient to rest in bed or on a couch for one or two days at anyrate.

Then the wound needs protection from irritation of its surface, from atmospheric influences, and for this purpose a dressing is applied. It is commonly supposed that some application should be placed on the wound to promote its healing, or something to "draw" out of it any inflammation that may arise. Hence the use by the public of all sorts of healing ointments, white zinc ointments, basilicon ointment, and so forth. It may be taken as a general rule that this is entirely erroneous. Such applications are entirely discarded by modern surgeons. If the person be in a good state of general health, the natural reparative powers of the body are perfectly sufficient for all healing purposes. The all-important point is to give nature a full opportunity for doing her own work by keeping the wound clean. The applications used now are almost entirely such as are designed to accomplish this purpose by preventing decomposition occurring at the site of the wound, which decomposition is set up by dirt in the wound or by particles deposited from the air, as explained in Section XIII. p. 384. Such applications are considered at length in Part III. Section IX. p. 910, and are called antiseptics. Antiseptic solutions are employed to wash the wound, and the commonest in use are the carbolic acid lotion, 1 part in 40 of water (p. 910), or the lotion of sulpho-carbolate of zinc (p. 911), or the lotion of boracic acid (p. 911), or permanganate of potash solution (p. 912), or a weak perchloride of mercury solution (1 in 5000, p. 912), or the iodine solution mentioned above. If the dressing is soaked in any material it should be one of these. But a perfectly dry dressing is the simplest, and is often to be preferred, and ought nearly always to be so in the case of clean-cut wounds. At the same time the dressing should be of such a nature, and should be so applied, that it will not cause any discharge to be retained, but will permit it to escape or will absorb it—lick it up. For such a purpose nothing is better than the absorbent wool or gauze now obtainable from every druggist. Such gauze is now obtainable impregnated with corrosive sublimate, or boracic acid, or eucalyptus, or other antiseptic. For domestic and popular use nothing could be better than this; a layer—dry—would simply be applied over the wound and would be secured by a roller or triangular bandage. An excellent oily application is made with 3 parts of olive-oil and 1 part of terebene. A piece of lint is soaked in this and placed over the wound and is then covered with a dry piece of lint or a layer of absorbent cotton, the whole being secured by a bandage. Simple water dressings are seldom desirable, since they promote decomposition, and the wound thus becomes foul-smelling.

It remains to be added that surgeons now always provide for the escape of discharge from a wound, and take care not to apply dressing in a way to prevent the escape of any matter that may form. In the case of deep wounds a piece of fine india-rubber tubing is passed into the wound, so that its one end is at the very bottom of the wound and the other end projecting. This provides an escape for any matter or fluid that would otherwise accumulate. As the wound heals from below, the tube is made shorter and shorter, till it may finally be removed altogether.

The Redressing of Wounds.—After a wound has once been properly cleansed and dressed it is well to leave it undisturbed for several days, undoing the dressing every day being only a cause of irritation, except in special cases. If the wound has been clean cut and is likely to heal readily, it should not be disturbed for four or even six days. If the parts, however, have been bruised or torn, earlier redressing will be necessary for the removal of matter and any separated parts of the tissue. Probably every second day will be sufficient, though more frequent redressing is necessary when there is much discharge. Each case, however, must be judged by itself,

the rule being that so long as the part is comfortable, and pain, or heat, or throbbing is not arising, it may be left alone. When the wound has been stitched, a few of the stitches are removed on the third day, others perhaps a day later, and so on. In undoing the dressing, no roughness should be allowed. If the dressing adheres, it is to be softened by a stream of water, carbolized or iodine water, and the lint or cotton soaked till it slips off of itself. A fresh dressing should be already prepared, and after the wound has been well bathed with the antiseptic solution, reapplied.

Subject to the above explanations regarding the general treatment of wounds, we may now give brief directions for the treatment of each of the varieties of wounds mentioned.

The Treatment of Incised or Clean-cut Wounds.—Having stopped the bleeding by raising the part, by using cold water, by firm pressure for a minute or two with a small piece of dry lint, or lint soaked in cold water, or in water tinged to a light sherry colour with tincture of iodine, or by some of the other methods noted in detail on subsequent pages for cases of serious bleeding, the person must proceed thoroughly to clean out the wound, removing all clots of blood, all dirt, fragments of hair, or other foreign matter. This is to be done by a gentle stream of cold water, or carbolic acid lotion, or the iodine water already spoken of. The cut surfaces must then be brought carefully and accurately together and held so by strips of adhesive plaster, stitches being preferable if anyone competent to insert them be present. A dry piece of lint or absorbent cotton, or lint soaked in the oil and terebene mixture (p. 971), is laid over it, then another larger piece placed above it, and the whole secured with a roller or triangular bandage. If the wound be on the arm or hand, the limb is secured by a broad sling (p. 962). In the case of a finger or a wound near a joint a splint should be applied. A piece of thick cardboard, cut of a suitable size, covered with a layer of absorbent cotton, will suit, and it is secured by the bandage. The patient should rest if the wound is at all severe. Redressing is not to done for four or six days, and subsequently every second or third day if needful. In the event of much pain, swelling, &c., arising, it may be advisable to remove the dressings, and if the wound seems much inflamed, cold or iced water cloths should be applied for ten minutes or so at a time at intervals of an hour or two till the pain and swelling are relieved. If the bulging of the wound seems to indicate any fluid retained within it, a strip of plaster should be removed to permit of its escape. The gentle insertion of a fine probe at one corner of the wound will permit of the escape of such fluid; a blunt-pointed knitting-needle, previously cleaned by being dipped in boiling water, would suit. The dressings would then be reapplied *lightly*.

The Treatment of Punctured Wounds.—These wounds are to be treated as detailed above for clean-cut wounds, with one notable exception—*the lips of the wound must not be closed, but kept open.* It is so difficult to ensure the thorough cleansing of such a wound that provision must be made for the escape of fluid or matter from the bottom of the wound. The lips of the wound are, therefore, to be kept *slightly* apart by the insertion of a very small piece of absorbent cotton or lint. If in two or three days there is no sign of any fluid, the wound is then allowed to close.

The Treatment of Bruised and Lacerated Wounds.—In these cases bleeding being arrested, and in such cases bleeding is comparatively slight, the wound must be very effectively cleansed. If this is necessary in clean-cut wounds, it is more necessary here, where death of tissue and decomposition are almost certain to occur. No attempt is to be made, however, to close the wound by strapping or similar method. If pieces of the tissue have been torn or pressed out of position, without being wholly separated from the body, they are to be gently replaced, care being taken that they and the parts to which they are restored are perfectly free from foreign particles. The cleaning should, in such cases, be done with the iodine water or other antiseptic. A layer of lint or absorbent cotton, soaked in the antiseptic, is then placed over the wound, and covered with a piece of oiled silk to prevent the dressing becoming dry. If the terebene and oil dressing is used, it should be covered with a layer of absorbent cotton, no oiled silk being necessary. A lightly-applied bandage then secures the whole. The part must be kept absolutely at rest. Probably in two days redressing will be necessary, and if there is much destruction of parts, more frequently.

The Treatment of Wounds of the Head.—Very special care requires to be bestowed on all injuries to the scalp, the risks of inflammation, suppuration, and erysipelas are so great. Here, if anywhere, there is no safety except in the strictest possible cleanliness. Even the

coolest person is apt to lose his equanimity at the sight of a mass of hair matted together by clotted blood, from under the edge of which a red stream trickles, and is likely to think that the best thing to do is to cover the whole thing up out of sight, and leave it to providence. This is just the course that must never be adopted. The masses of hair must be quickly parted, till the whole extent of the wound is clearly shown. If the bleeding be little, the person should proceed at once, by means of cold water and pieces of *clean* lint or cotton, to remove all particles of congealed blood, not over the wound only but from every part of the scalp. This must be done thoroughly once for all, and the person must not desist till the hair is completely cleaned, disentangled, and then dried. Then for an inch or so all round the wound the hair should be removed quite close to the scalp by a pair of sharp *clean* scissors. The wound itself must be carefully cleaned by a stream of cold or preferably iodine water. If blood is still oozing from it, a pad of lint wrung out of the water is to be firmly pressed upon it for a minute or two. If the blood be welling out of the wound, the time necessary to complete the cleansing process is too long, and the bleeding must be arrested at once. It will be well therefore to clear a space at once round the wound with the scissors to enable one to get at it thoroughly. But this is not to be done by slashing, haphazard snips, needlessly cutting away large masses of hair. When the wound has been effectually got at, a pad of lint wrung out of cold water or iodine water is pressed firmly into the wound, and if an assistant be at hand he will hold it so, while the person taking charge proceeds to disentangle the hair and clear away clots and foreign material. When all this has been done the wound is to be closed and dressing applied. All clean-cut wounds should be closed as accurately as possible. It is not easy to do this with plaster, because of the difficulty of it securing a hold on the hairy scalp. A surgeon might or might not use sutures, but certainly no unskilled person ought to. The person will do what he can by means of plaster strips, and perhaps by aid of the pressure of small pads of lint on each side of the wound, to bring its lips together. He should apply a dressing of lint soaked in some of the antiseptics named, but preferably terebene and oil or carbolic acid oil, covering lint soaked in any watery solution with oiled silk, but the oily preparation with a dry layer of lint or absorbent cotton, and then fix all with a suitable bandage (see p. 960). If the wound be bruised or torn, no attempt will be made to close it, the antiseptic dressings will be applied, and redressing practised as often as necessary to keep the wound perfectly clean and free from smell. At one time it was not uncommon to pour on the wound friars' balsam, or other sticky substance, to seal it up and help to arrest bleeding. This is only too apt to cause the retention of discharge and dirty material, and is not at all advisable.

The treatment of wounds has been entered into in some detail. This has been done, it is needful to say, not to enable anyone to do without the aid of a surgeon in more than the class of very slight wounds which most people regard as too trivial to require such aid. For anyone who is within reach of such skilled help, and yet attempts to treat a wound of any severity, commits what is really a grave error. It is much wiser, and in the end much more economical, to get immediately competent assistance, when it is at hand, than to be compelled, after some time and when the wound has failed to heal, to resort to a surgeon, when the simple healthy wound has been converted by some excusable error or some circumstance that an unskilled person could hardly be expected to notice, into an unhealthy sore, inflamed by irritation and ulcerous by decomposition. But the author is compelled to have regard to the fact that this book will be in the hands of very many who are remote from medical aid, to whom from geographical or other circumstances any skilled help is simply unobtainable, and who must either attempt to treat such injuries as they best can or let them alone to "go to the bad" or to get well, as circumstances or fortune may determine. It is ridiculous to say that it is useless to attempt to lessen the hardships which such persons are constantly called upon to endure. If it is almost universally admitted, as it now is, to be proper to teach the principles of first aid to the injured to those who live in the midst of large communities, where surgeons are to be found on every hand, it ought to be even more readily admitted to be desirable to place even more extended information within the reach of those isolated from all such resources. Therefore the author has considered his work would not be properly done, unless he stated as clearly and simply as he could the broad general principles which all surgeons accepted as the basis of their practice, and leave these to be applied to each

particular case as the common sense of the individual, guided by them, should determine.

The Treatment of Bruises.—The term bruise or contusion (Latin *contundo—con,* and *tundo,* I beat) is restricted to such injuries as are produced by severe pressure, or by a blow from a blunt instrument, or by a fall on a hard substance, when the skin is not broken, or only very slightly broken, as when an **abrasion** has been caused, that is, when the scarf-skin has been removed and the sensitive bleeding true skin uncovered. Bruises may be of all degrees of severity, from that caused by a pinch where only the skin is squeezed sharply, to that which extends into the layers of fat beneath the skin, causing rupture of many small vessels and injury to other deep parts, and to that degree in which the whole tissues of the part may be reduced almost to pulp. Large vessels may be ruptured and extensive bleeding occur, leading even to the producing of pulsating blood tumours, forming a **false** or **diffuse aneurism** (see p. 244). The important point between a bruise only and a bruised wound is that the former is covered by skin which protects the injured tissues from external influences, and especially from the attack of atmospheric agencies, leading to decomposition and suppuration, while the latter is open to all such unfavourable influences. Of so much significance is the protection afforded by the unwounded skin that very serious and extensive bruising of parts may occur, may produce much swelling, inflammation, and pain, and yet recovery occur without the slightest formation of matter or apparent loss of tissue. It will be evident, then, that any method of treating a bruise which breaks through the protective covering of the skin will be highly improper. Nothing could well be more injudicious than the use of leeches or the lancet to reduce the swelling by removal of the effused blood, since thereby a way would be opened for the entrance into the injured tissues of the agents of putrefaction. Yet leeches used to be, and in some classes of society are yet, the resort for such a bruise as that which produces a black eye. Besides the error already noted which such treatment commits, there is another. A leech does not remove blood already poured out from the vessels and diffused among the soft parts, but it opens other blood-vessels and removes fresh blood. The purpose of their application is not served, and the wound they cause adds an altogether unnecessary element of risk.

The first signs of a bruise are redness, swelling, and discoloration. They are all due to the injury done to the soft parts, and specially to the blood-vessels. The swelling and discoloration which follow are caused by the blood poured out of the damaged blood-vessels, and to the outflow of serum from the blood and other elements of blood for the repair of the damage. The discoloration is produced entirely by the effused blood. It may occur within an hour or two of the injury, if it is the surface blood-vessels that are injured, or not for a day or two if deeper parts are injured, while the skin has escaped. Thus it may not appear for twenty-four hours, if the tissue lying immediately beneath the skin is damaged, and will not appear on the surface for some days if the injury has damaged deeper parts, muscles and the tissues between them. In the latter case the discoloration very frequently appears at a considerable distance from the seat of injury, because the escaped blood has gravitated downwards from the injured part.

The technical term applied to this poured-out blood is **ecchymosis,** or **extravasated blood.** Ecchymosis is derived from the Greek *ekchymōsis,* from *ek,* out, and *cheo,* I pour, and the word extravasated is Latin, from *extra,* outside of, and *vasa,* the vessels.

The discoloration resulting from a bruise is at first dark-purplish, and its margin is well marked. In two or three days the margin is spread and less defined, and the colour is more violet in tinge. About the fifth day it is green, in a day or two more yellow, and in one or two more days it has disappeared. The margins show these changes sooner than the centre, so that while the chief part of the discoloration is still dark in colour, bluish or green, the margins are greenish-yellow or yellow, and an irregular mottled appearance results when the blood has been irregularly distributed in the tissues. These changes of colour are due to changes going on in the effused blood, part of the blood being quickly absorbed by the lymphatic vessels (see p. 200) and passed back into the circulation, and undergoing also a bleaching process, as it were, while it lies among the tissues. As the blood and other fluid are absorbed the swelling gradually diminishes, and by the time the colour has become yellow it has almost disappeared. The repair of the parts damaged by a bruise is practically identical with the process of repair already described as going on when a wound heals by first intention. Of course the result of a bruise may be such destruction of

tissue that a collection of matter results, which would require removal by an incision; and again in persons of depressed health a bruise might end in an abscess, sloughing of the skin, and so on, which in a vigorous healthy person would have healed without trouble.

A considerable amount of pain, and some degree of inflammation and throbbing, attend a bruise. The degree of pain will largely depend on the amount of swelling, implying more or less pressure on nerves and other sensitive structures, but the inflammation usually soon subsides.

The Treatment of Bruises.—Reasoning from what has been said there are two plain indications of what should be the aims of treatment. First, the swelling and discoloration being the result of the breach of blood-vessels in or beneath the skin and the escape of blood, the immediate thing to do is to stop the bleeding; and if that can be done speedily the swelling and discoloration will be all the less. Second, after all bleeding has ceased, the swelling and discoloration gradually disappear by the removal of the poured-out material by the agency of the lymphatic and other vessels. Any means that will stimulate the vessels to this work will shorten the process.

First, then, what will arrest the bleeding? Cold applications.

Second, then, what will stimulate absorption? Hot applications.

Immediately a blow or fall has been sustained, likely to lead to swelling, &c., resort should be had to cold water. The part should be diligently bathed, the sponge or cloth soaked in cold water being laid on, only for an instant, and then renewed, to maintain the cold. The part affected should meanwhile be held high, not allowed to hang. No delay should be allowed to occur till one learns whether swelling is going to take place or not. In very many cases the swelling may be almost prevented if the cold water be instantly applied, and the more surely will this be the case the more the injury is on the surface, where the cold can act quickly, the less surely the more deep-seated it is. Such applications also greatly relieve the pain and diminish the chance of subsequent inflammation.

In households where cold water is always at hand, a very great amount of needless pain and disfigurement would be saved children if mothers and nurses would instantly rush to the cold water, and not waste time condoling and sympathizing with and kissing the unfortunate child. The cold should not be continuously applied for a long time. A few minutes are all that is necessary, and then after a few minutes' interval another two or three minutes' application. All other popular applications, a coin, a piece of raw beef, derive any value they possess—which is slight at the best—from their being cold. Some astringent lotions are useful, when applied immediately, in diminishing the escape of blood. The arnica lotion is one specially in popular favour, but it should not be employed if the skin is at all broken; and another which seems to be much more useful is the extract of witch-hazel, or hazeline, and which is sold in America as Pond's extract.

After measures have been taken to arrest the bleeding, the bruised part should be kept at absolute rest for a time, and nothing further done for some hours at anyrate to remove any swelling that may have occurred. Specially if the bruised part be in the neighbourhood of a joint must absolute rest be insisted on, not for an hour or two, but till all swelling, pain, and tenderness have passed away. The attempt to use the part earlier than that will certainly be followed by an increase of the swelling.

After the lapse of some hours one may endeavour to hasten the diminution of the swelling. For this warm applications are best, gentle bathing of the part with warm water being the simplest; and if this be repeated at short intervals a speedy restoration to the natural appearance may be expected. Any increase of swelling or pain would be an indication for stopping it and resorting rather to cold. Rubbing the part with one kind of stimulating lotion or another is frequent, but of somewhat doubtful value. Probably of much greater value would be gently but firmly stroking and manipulating the part in the manner described under Massage (p. 772), but such stroking and manipulation ought never to be so performed as to excite pain or renew inflammation.

The employment of such measures, the immediate use of cold, and the use later of warm bathing, is the appropriate means of dealing with a **black eye**; and the same methods should be employed for a strain or sprain of ankle, wrist, &c., combined with perfect rest in a raised position.

A caution is necessary. Where a bruise is very extensive and severe, cold must be applied with great caution and judgment lest the tissues, already much damaged, have their vitality still further lowered. Many very extensive bruises

undergo repair with wonderful completeness, if the skin be not wounded anywhere. Probably in extensive bruises the only assistance an unskilled person could render would be to have the person placed comfortably in bed, the bruised part being most carefully handled and supported equally on all sides. If the person has to be carried for some distance, the care with which this is done very often determines the issue, favourable or otherwise.

THE ARREST OF BLEEDING.

The Distinction between Bleeding from an Artery, a Vein, and Capillary Vessels.— The distinction here indicated is one between the kinds of vessels from which the blood is escaping; and if reference is made to pp. 225, 226, the differences will be made plain. The capillaries are exceedingly fine vessels, too minute to be made out without the aid of a microscope. The arteries are of a great variety of size in cross section, but are thick-walled resisting tubes, the smaller ones markedly contractile, the larger ones specially elastic. The larger ones remain open when they are cut across. The veins on the other hand are thin-walled, collapsing when empty, but as readily widening out to a large size when filled with blood. The arteries, consequently, will resist closing by pressure to a considerable extent, while the veins will be easily closed thereby, and the capillaries are quite readily compressed. The flow of blood will be quite easily stopped by comparatively little pressure in veins and capillaries, while that in arteries will persist despite a considerable amount, specially when they are deep-seated and protected by surrounding muscles and other soft parts. From capillaries, and also the more minute arteries and veins, the blood will ooze out, though when the wound occupies a large area much may be lost in a comparatively brief period. A wounded artery may be distinguished from a wounded vein, when both are of a larger size, by the manner in which the blood flows, and its appearance. From a wounded artery the blood will issue in jerks or spurts, corresponding to the strokes of the heart, while from the vein it will pour in a steady stream. The blood from an artery is of a brighter, more scarlet hue than from a vein, from which it is darker or more purplish in colour. Another point it is of importance to notice. From both sides of a wounded vein the blood escapes, but more particularly from the end nearer the extremity of the body, the end farther from the heart, while from a wounded artery the blood escapes only from the side nearer the heart. For the blood in an artery is flowing from the centre of the body to the extremities, while it is being returned in the vein from the extremities to the heart. It is often of importance to observe these distinctions, because, in the event of pressure by a pad or a bandage being necessary to stop the flow, it is clear that in the case of an artery it should be applied on the side of the wound nearer the heart, while in the case of a wounded vein the opposite course will arrest the chief bleeding, or hæmorrhage, as it is called, from the Greek *haima*, blood, and *rhēgnymi*, to burst.

Bleeding is arrested naturally by the sealing up of the wounded vessels by the clotting of the blood at the mouths of the vessels, round about and over them, and within them up to the level of their first branches. Besides, there is poured out of the wound a coagulable material or lymph, further sealing them, and subsequent changes take place, similar to those for the repair of a wound, by which they are effectually closed. As part of the process of repair, the vessels are permanently closed by the formation of connective tissue, such as takes place in a wound, so that after a time nothing is left of the part of the vessel where the wound occurred but a fibrous cord, this change taking place in the whole length of the vessel up to its first branch beyond the seat of injury. Before such changes have had time to occur a renewal of the bleeding may take place by extra pressure in the vessels, causing the sealing to give way and displacing the clots, or by rough handling; and in the case of large vessels it may occur several days after the injury. In such cases it is called **secondary hæmorrhage.** An important element in the natural closing of a vessel is the elasticity of its walls, which, when it has been completely divided, leads it to retract within the wound, when its mouth is closed by the pressure of surrounding tissues. There is, consequently, less bleeding as a rule from an artery completely divided than from one only wounded, since in the latter case the artery is unable to retract.

The Methods of Stopping Bleeding.— The various means of arresting hæmorrhage are as follows:

Raising the Part;
The Application of Cold;
The Application of Pressure;
The Use of Astringent Substances or Styptics.

How does raising the part help to stop bleeding? Suppose blood is flowing from a wound in the wrist. It is plain that if the arm be allowed to hang, a plentiful supply of blood will readily pass down the limb to the wounded part, while the blood returning from the hand will return up the arm less readily, and there will be a determination of blood to the wound; while if the arm be held high up less blood will pass up to the wound, and the blood returning to the heart will do so more readily, with the result of a great diminution in the escape from the wound. Similarly if the foot or lower limb be wounded, the person should lie down or recline, and have the leg raised above the level of the head. Another thing to be attended to is the removal of any hindrance to the ready return of blood to the heart from the injured part. If, for example, a wound has been inflicted on the lower part of the leg, or if a varicose vein has burst, the pressure of a tight garter or similar contrivance will delay the return of blood up the limb and make the bleeding very free. Similarly in the case of bleeding from the hand or arm, clothing tight at the arm-pit, through which the vessels pass, will greatly aggravate the bleeding. When the part is raised, then, all tight clothing should be loosened. Take as another illustration of the same thing, bleeding from the nose. The tendency is for the person to hang the head to prevent the blood flowing on to the clothing, whereas the head should be held high. If the person wears a tight collar, the hanging of the head causes the veins of the neck to be pressed upon, the blood is prevented freely returning from the head, and the bleeding is all the more free. In addition to holding the head up, therefore, see that everything round the neck is loosened. Cold diminishes bleeding by causing the vessels and tissues to contract, and astringent substances like borax, alum, tincture of steel, tannin, friars' balsam, matico, act in the same way. Astringents also coagulate fluid parts of the blood and promote the formation of a scab. Collodion, when it sets, causes contraction of the parts, and also aids in sealing the wounded vessels.

But none of these means of stopping bleeding is equal to that of properly applied pressure, by which the bleeding vessels are forcibly closed. It is applicable to every sort of bleeding, at least from the surface of the body. Pressure may be applied directly on the wound itself in every case, altogether irrespective of the nature and size of the wounded vessels. In many cases the pressure of the thumb laid directly over the wound will be sufficient, and if the pressure be maintained for a little time that may be sufficient to cause the bleeding to cease entirely. If a small pad of lint, or a piece of cloth made into a pad, a strip of handkerchief rolled up, for example, be laid just on the wound and be pressed into it by the thumb, or held firmly on it by a bandage, the arrest of bleeding will be still more satisfactory. But when the bleeding is profuse, the mistake commonly made is to cover over the wound with large pieces of cloth, handkerchiefs, bandages, &c. The result often is that the pressure is spread over a large area, is not properly adjusted over the wounded vessels, and under the mass of coverings the bleeding may go on uninterruptedly. The pad, then, should never be very large. It need never be any larger than is just sufficient to cover the wound, and then it is easy to concentrate the pressure upon the bleeding surface. But while pressure thus applied will be sufficient to arrest the bleeding for a time, it is often insufficient for its permanent stoppage. If a large artery has been wounded the pressure might be kept up for a time, but as soon as it is removed it would start afresh, because the large vessel has not had time to close, and gapes again as soon as the pad is removed. In such a case if pressure were to be maintained long enough to permit complete sealing to occur, the time would probably be so long and the pressure so considerable that the vitality of the tissues would be seriously impaired. Such a method, therefore, while highly satisfactory for a limited time, must give way to others for the permanent closure of the wounded vessel. These methods will be noted in the paragraphs on arterial bleeding. We shall now note the steps to be taken to arrest bleeding under various circumstances.

To Arrest Capillary Bleeding, elevate the part, apply cold water, or the iodine water, mentioned on p. 965. If that is not sufficient fold a piece of lint into a small pad, just enough to cover the wound, and exert firm pressure upon it for a little. The pad may be secured by a bandage. When it is to be removed, it must be thoroughly saturated with water, so that it is washed and not torn off.

To Arrest Bleeding from a Vein.—Follow the above rules, but whenever the bleeding is of any amount apply pressure without delay.

To Arrest Arterial Bleeding.—When the smaller sized arteries are wounded the appli-

cation of cold and simple pressure is usually enough to stop all bleeding, not only for the time but also permanently. But the larger arteries, if divided, allow blood to escape so rapidly that the bleeding will be sufficient to cause death in a minute or so if uncontrolled. In the case of the smaller vessels there is time to expose the wound, to clean it, to ascertain exactly where the wounded vessel is, and to apply appropriate pressure directly over the spot. But in the case of the larger arteries one must arrest the bleeding immediately in some way or another, and take time subsequently to examine the wound. Then again the place where the artery is wounded may be so deep that it is difficult to get pressure properly applied to it, and although one has applied pressure on the surface the blood may be forcing its way among the tissues. It is clear that the bleeding at the wound would be arrested if the main trunk of the vessel were closed. Thus, suppose bleeding occurring at the palm of the hand which resists all the simple means of stopping it, it is evident that if one could block the main vessel at some part of its course through the arm, the supply of blood to the hand would be arrested and the bleeding would cease. Of course if this blocking were to be maintained for a long period death of the parts deprived of their blood-supply would arise. It must never be forgotten, therefore, that this arrest of the circulation is only resorted to in the emergency, till skilled assistance can be obtained to apply appropriate treatment. Now severe accidents wounding large vessels of one limb or another are not uncommon in large public works, in the harvest field, &c., and there is no manner of doubt that many lives would be saved annually if this method of temporarily arresting hæmorrhage were well known. Even apparently simple accidents frequently end in death from ignorance of such procedure. For example, in the city of Glasgow, a year ago, a beadle of one of the churches, in cleaning a window, accidentally broke a large pane. The glass tore a deep ragged wound across one wrist, opening one of the chief vessels of the forearm. These vessels are so near the surface, and so easily commanded, that, had the man known how, he could easily have stopped the bleeding by his uninjured hand. But he was completely ignorant, and ran to the nearest doctor's house. The doctor was not at home; and he ran to another, and so from one door to another till, from loss of blood, he fell exhausted and speedily died. The smallest amount of knowledge on his own part, or on that of the occupants of the various houses he called at, would have saved his life. We shall, therefore, point out the direction of the chief vessels of the limbs, noting the places where the main trunk comes near enough the surface to be readily commanded, and then show how, by the simplest possible contrivances, bleeding, even from the largest vessels, can be arrested for a time till medical aid can be obtained.

To Arrest Arterial Bleeding from the Arm.—The course of the main artery of the arm is shown in Fig. 367, reproduced from p. 227, where it is more fully described. The artery enters the arm through the arm-pit, midway between the front and back folds, and its course is indicated by a line drawn from the middle of the arm-pit over the arm to the centre of the elbow in front. If one places the thumb on the inner side of the upper arm, midway between the arm-pit and the elbow, and on the line that has been indicated, and if one presses from within outwards, one will press the artery against the bone; its beating will be readily felt, and by increasing the pressure the vessel can be closed. This would stop entirely any bleeding occurring in the forearm and hand, so long as the pressure was maintained. The artery is easily reached, because it is not buried among muscles at any part of its course. In Plate XVI. fig. 11, the fingers are seen pressing in the direction indicated for the purpose of controlling bleeding. The same figure shows another situation in which pressure may be exerted to arrest the supply of blood to the arm. The main trunk of the arm is a continuation of what is known as the subclavian artery (p. 226), and on its way through the chest to the arm it passes behind the collar-bone. In this situation, by pressing the fingers behind the centre of the collar-bone, its pulsations are easily felt, and if

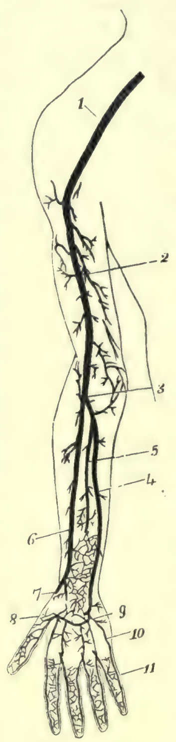

Fig. 367.—Arteries of the Front of the Arm.

1, the axillary artery; 2, the brachial artery, dividing at 3 into 6 the radial, and 4 the ulnar artery, the ulnar giving off a deep branch 5. 7 the radial artery, winding round the back of the wrist to reappear at 8. Between 8 and 9 the superficial arch in the palm giving off branches, as 10, to end along the side of the finger, 11.

very firm pressure be exerted backwards, as well as downwards, the vessel may be compressed against the first rib. Pressure need not be exerted here unless when the wound of the arm is very high up. The handle of a large key, first padded with a piece of cloth, may be used instead of the fingers.

Now while pressure with the fingers is the safest and best method of stopping the flow of blood in an artery, they readily become fatigued; and if any time elapses before aid can be obtained, it becomes necessary to employ some other means. A pad may be placed over the vessel and firmly pressed upon it by means of a bandage. The pad and bandage may be made by the simplest things. A stone wrapped up in a handkerchief to prevent its hard surface injuring the skin may be employed, and secured by another handkerchief applied like a triangular bandage (see p. 962), or a long neckerchief may have a large knot tied upon it, and may then be fixed round the arm, so that the knot presses on the artery (see fig. 6, Plate XVI.), which also shows how the requisite degree of pressure may be employed by slipping a piece of wood, a knife, &c., under the neckerchief after it has been tied, and twisting it up.

To Arrest Arterial Bleeding from the Hand it may not be necessary to compress the main artery of the arm. Make a firm pad with a pocket handkerchief, in which a small smooth stone is wrapped: let this be placed in the palm, and let the patient close the hand tightly over it; then secure the hand in this position by means of a bandage. It may also be stopped by the pressure of a pad across the front of the wrist to close both vessels.

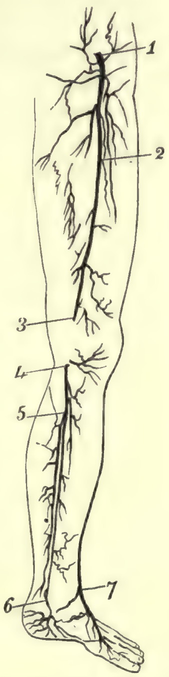

Fig. 368.—The Arteries of the Lower Limb.

1, the femoral artery, passing deeply into the thigh at 2 and winding into the ham at 3; 4, its posterior tibial branch, which passes to the ankle at 6, giving off a large branch at 5; 7, part of the anterior tibial artery shown in Fig. 125.

To Arrest Arterial Bleeding from the Leg.—The course of the main artery of the leg is shown in Fig. 368, reproduced from p. 228. If the leg be turned somewhat outwards and the knee be half bent, a line drawn from the middle of the groin over the thigh to a little above the inner side of the knee-joint indicates its course. Such a line is shown in figs. 1 and 2 of Plate XVI. In the upper third of the thigh, the vessel is not covered by muscles, but lies under the skin and fat. Pressure exerted here will close the vessel and so arrest bleeding lower down. Fig. 10 of Plate XVI. shows how the thumb of each hand may be placed alongside of each other to accomplish this. Here certainly it would be difficult to maintain efficient pressure for any length of time, and the use of a pad of some kind is necessary. Fig. 2 shows the application of a knotted cravat, twisted up by means of a knife to accomplish the end desired.

When, however, the bleeding occurs in the foot or lower leg it is not always necessary to block the vessel so high up. From the inner side of the knee the vessel passes back into the space behind the knee-joint, the ham, and pressure may be exerted quite effectually here by placing a roll of bandage, a stone wrapped up in cloth, &c., in this space, and tightening it up as shown in fig. 9, Plate XVI.

To Arrest Bleeding from the Head and Neck, keeping the head high, employ cold water, and apply firm pressure directly over the wound. Fig. 369, reproduced from p. 227, shows the position of the main arteries. When the head is thrown back and to the side the line of one of the chief muscles of the head and neck is shown in relief, and this muscle covers the main

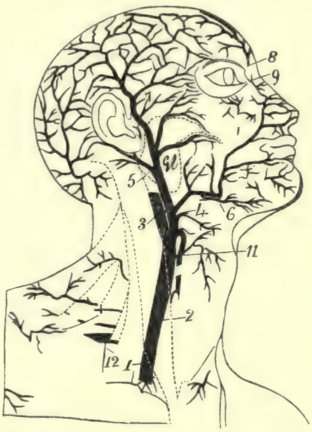

Fig. 369.—Arteries of the Head and Neck.

1 and 2, the common carotid artery, 2 being the part covered by muscle as indicated by dotted lines; 3, the internal, and 4, the external carotid. Some branches of the external carotid are shown, 5 to parts behind the ear, 6 to parts under the chin, 7 to the side of the head, and 9 to the nose. 8 points to a branch of the internal carotid which comes out from within the skull above the eye and is distributed over the forehead. 11 is a branch passing down to the front of the neck. 12 points to part of the subclavian artery. *Gl* shows the position of the salivary gland.

artery and protects it from injury up to the level of the angle of the jaw, and beyond which the artery lies less deeply, where it divides. Firm pressure here will be necessary if the arteries beyond be wounded. In cases of cut throat branches from these vessels are often wounded, but bleeding may be arrested by direct pressure on the wound, and by pressing the edges of the wound together between fingers and thumb.

To Arrest Bleeding from the Nose, let the person sit erect, holding the head high; let a large sponge soaked in cold water be held over the nose. If this is not sufficient, as it commonly is, let the nostrils be held firmly for a little, or let cold water, or cold water with borax or alum dissolved in it, or the iodine water mentioned on p. 969, be gently injected by means of a syringe up the nostril. If this is still insufficient the nostril should be plugged by means of a piece of lint, rolled up in the shape of a cone and pressed up, small end first, into the nostril, the large end projecting outwards. Sometimes it is necessary to plug not only the external openings of the nostril, but also the internal opening, that leading into the back of the throat. This, however, can be done only by a surgeon.

Tourniquets (from the French *tourner*, to turn) are appliances used to check bleeding. The pad and bandage, tightened by the twisting of a piece of stick, is a rough and ready made tourniquet; and in Plate XVI. figs. 3, 4, and 7 show various forms. The ordinary form of tourniquet consists essentially of a pad to be placed over the artery to be compressed, of a strap to fix it, and a screw to tighten it. Fig. 4 in the plate shows Petit's tourniquet. The figure shows it provided with a pad, but besides the screw it may consist only of a strap of stout webbing and a buckle. A roller bandage is then used as pad. It is unwound a little; the roller being placed over the artery the end is passed once or twice round the limb to fix the bandage. Then the strap is put round over it, so that the screw is on the opposite side of the limb and the buckle between the screw and pad. The strap being pulled through the buckle and fixed, it is then rapidly tightened by turning the screw. This must be done rapidly, else the veins would be compressed a little before the artery, being nearer the surface than the artery; the blood being prevented returning from the limb before it was stopped passing down into it, the limb would be overcharged with blood. Fig. 3 of the plate shows a tourniquet made of a piece of wood, through slits in which the strap is passed, the strap having a pad fixed to it. After the strap is tied it is rapidly tightened by twisting it up with a piece of wood. Fig. 7 of the plate shows a tourniquet made of a long india-rubber band, as thick as one's little finger. It passes through a block of hard wood, and a channel is cut in the block of such a size that the india-rubber can pass into it only when it is well stretched, and it prevents the band from slipping as soon as the stretching force is removed. In fig. 8 it is shown applied. The rubber band is passed once fully round the limb, and then both ends are brought round, and are so strongly stretched that they are able to pass into the groove where they are gripped.

Bleeding from a wounded artery is permanently arrested by the artery being tied either at its wounded end or in its course at a little distance from the wound. Fig. 5 of Plate XVI. shows a pair of artery or catch forceps. By means of these the end of a cut artery is picked up. The forceps being then shut, the spring keeps them so, and the mouth of the vessel is kept closed till a ligature is put round it and tied, after which they are released.

It must be observed that it is never necessary to apply a tourniquet to stop bleeding from a vein. Direct pressure over the wound by a pad held firmly by the fingers, or a pad secured by a bandage, will always be found effectual.

POISONED WOUNDS, INSECT STINGS, SNAKE BITES, AND OTHER KINDS OF POISONED WOUNDS.

Poisoned Wounds are dangerous out of all proportion to the size or situation of the wound, and out of all proportion also to the amount of poisonous material which has gained entrance to the body. For the poison is almost invariably of animal origin, capable of multiplying in the tissues and blood, and, just as "a little leaven leaveneth the whole lump," is capable of profoundly affecting the whole body. The description given in Section XIII. (p. 384) of the action of minute organisms is applicable to the way in which poison introduced by a wound affects the body. The material introduced sets up changes in the part of the nature of fermentation, and may be limited to the immediate surroundings of the wound, leading only to the formation of abscesses or ulcers, but may extend along the blood and lymph channels, reaching glands and setting up inflammatory action in them, and perhaps leading to changes

TEMPORARY TREATMENT OF FRACTURES.

in the blood, showing themselves in fever, diarrhœa and all the symptoms of blood poisoning (p. 236). Now the poisonous material may be on the instrument with which the wound was inflicted. For example, wounds received by medical students in the dissecting-room, by a surgeon performing a post-mortem examination, by a veterinary surgeon or others during the process of cutting up or removing the hide from an animal which has died of some disease, are all of a very serious nature, since the knife with which the wound was inflicted is smeared with the juices from the dead body, which are thus directly introduced to the tissues of the person. Insect stings, bites of venomous reptiles, &c., belong to the same class, but will be discussed separately.

The wound, however, may have originally been perfectly clean and healthy, and foul material may gain entrance to it later, and convert it into a poisoned wound. This may happen in an infinite variety of ways. A person with a wound upon the hands, however slight, who handled a foul sore or ulcer without precaution or came into contact with unhealthy discharges would run great risk. Similarly anyone who had dressed or assisted in dressing unhealthy wounds or sores of one person, and went straight to assist in the dressing of another person who had a perfectly clean and healthy wound, would be almost certain to infect the clean wound with material from the unhealthy one. Surgeons are now exceedingly careful and scrupulous in this respect, and adopt all manner of precautions, not only to ensure the thorough cleanliness of their hands and instruments, but also to ensure that their clothing may not be a source of danger. It is surprising how small a wound, a mere scratch and mere prick with a pin or needle, may offer sufficient entrance room to foul material. The author was awakened one night by pain and throbbing of his right thumb. By morning the whole thumb was red, swollen and tender, and a broad pink band of inflammation passed from the thumb over the wrist and up the front of the arm to the inner side of the elbow, where happily it stopped. This was acute inflammation of lymphatic vessels (see p. 206), due to a poisoned wound, but there was neither wound nor scratch apparent. But after a little thought the cause was clearly traced. He had accidentally pricked his thumb with a pin, a perfectly clean and harmless pin. But an hour or two later he had to treat at a public dispensary a large number of cases of eye disease, including several cases of a form of inflammation attended by copious discharge of a very contagious character from the eyelids. During the holding open of the lids with the thumb and forefinger, some of the infective material had crept into the minute and forgotten pin-prick, and though, immediately after the case had been treated, the hands had been carefully disinfected and washed, still enough had gained entrance to give trouble, though fortunately only for a few days. No one, then, can be too careful in dealing with foul sores or discharges, and no scratch or broken skin, however small, is so insignificant as not to need protection in the presence of such unhealthy wounds.

Some persons seem to be peculiarly invulnerable to risks of this description, while other persons are peculiarly liable. Undoubtedly also the tissues of some persons resist the operation of such morbid material more strenuously than those of others; and it is equally certain that the state of one's health at the time affects in a very marked way the degree of resisting power. Thus a person in depressed general health is much more apt to be affected by poisoning in a wound than another in robust health.

The symptoms that attend poisoning in a wound are redness, pain, and swelling in and around the wound, with the formation of matter, and perhaps the death and separation of some part of the tissues. Then the redness extends along the lines of the lymphatic vessels leading from the site of the wound up the limb, and these vessels are marked out by fine red lines, which, as the inflammation extends, become broader and merge in one another. These lines meet in the nearest gland, which may become inflamed and swollen also, and be hard and tender, and may end in becoming a collection of matter. Here the process may cease, but on the other hand, it may continue its course up the limb, and produce attacks of shivering, fever, and all the symptoms of blood poisoning, which need not be detailed here, since they have been discussed on p. 236. Reference also to p. 206 and p. 207 will explain the effects on lymphatic vessels and glands.

The Treatment of Poisoned Wounds.—In the first place what is to be done when a wound is received from an instrument known to be foul? It should be immediately thoroughly washed with a stream of clean water. If carbolic acid is at hand, or Condy's fluid, it should be added to the water. The corrosive sublimate solution (p. 912), supposing it to be at hand, would be the most useful. But in most cases some delay is inevitable, and meanwhile the

poison would be absorbed. Therefore the speediest method, and one always at hand, is to grip the part immediately above the wound as tightly as is possible, to arrest the circulation, and vigorously suck the wound with the mouth to remove the poison. As soon as possible thereafter it should be washed. Further to ensure destruction of the poison the wound should be touched all over its surface with lunar caustic (nitrate of silver). It should then be covered with a piece of lint smeared with vaseline, or carbolized vaseline, or soaked in carbolic oil. The lunar caustic destroys only a fine surface film of the tissue, and when this has separated a healthy wound is left. If any of the strong acids, nitric, for example, be at hand, it may be employed instead of the caustic. But this agent is so destructive that it must be applied with great care. The best way is to dip a piece of wood, the end of a match, if nothing better can be had, into the acid, shake off the drop that adheres and then pass the end lightly over the surface of the wound, care being taken not to touch any of the uninjured skin. The wound is then bathed with cold water and bound up as before advised. Another very effective method is to heat to *a white heat* the end of a knitting needle, or failing anything better, the end of a long nail, and pass it over the whole surface of the wound, then apply cold water dressing to subdue inflammation, and frequently renew it. If the iron be heated to a white heat the pain inflicted by the application is comparatively trifling.

In the event of a wound, believed at first to be quite clean, showing signs of having been poisoned, the dressing must be immediately undone. If a pustule or boil or abscess has formed, it should be freely laid open by a sharp knife, and every particle of matter cleared out, and the wound thoroughly mopped out with carbolic or other antiseptic lotion (p. 912). The raw surface might then be touched all over with caustic or strong carbolic acid, or other acid, washed again in a stream of cold water and then dressed as already suggested. Frequent antiseptic cleansing would be afterwards necessary. Treatment of further complications is sufficiently explained under the headings of blood poisoning and inflammation of lymphatic vessels and glands (pp. 236 and 206).

Now although these directions have been given to meet emergencies, and the case of those who are out of reach of medical aid, the consequences that may ensue are so grave, and their treatment requires so much constant care and skill and knowledge, that no delay should be allowed to take place and no trouble spared in obtaining competent medical aid.

Stings of Insects.—Bees and wasps are in this country and in America the insects which have the greatest number of victims by their stings. It is quite a common thing in summer to see recorded the narrow escape of a person from being stung to death, and now and again actual death of an adult or child. As regards bees these accidents seem to be most common about the time of the casting off of a swarm, and numerous are the instances reported of a swarm settling on a person's head, and being skilfully "hived" without the slightest injury to the person. Thus we take the following story of an old English bee-master, Thorley, as an illustration. "In the year 1717, one of my swarms settled among the close-twisted branches of a codling tree, and not to be got into a hive without help. My maid-servant being in the garden, offered her assistance to hold the hive while I dislodged the bees. Having never been acquainted with bees, she put a linen cloth over her head and shoulders to secure her from their stings. A few of the bees fell into the hive, and some upon the ground, but the main body upon the cloth which covered her garments. I took the hive out of her hands, when she cried out that the bees were got under the covering, and were crowding up towards her breast and face, which put her into a trembling posture. When I perceived the veil was of no further service, she gave me leave to remove it; this done, a most affecting spectacle presented itself to the view of all the company, filling me with the deepest distress and concern, as I thought myself the unhappy instrument of drawing her into so imminent hazard of her life. Had she enraged them all resistance would have been vain, and nothing less than her life would have atoned for the offence. I spared not to use all the arguments I could think of, and used the most affectionate entreaties, begging her with all the earnestness in my power to stand her ground, and keep her present posture; in order to which I gave her encouragement to hope for a full discharge from her disagreeable companions. I began to search among them for the queen, they having now got in a great body upon her breast, about her neck, and up to her chin. I immediately seized her, taking her from the crowd, with some of the commons in company with her, and put them together into the hive. Here I watched her for some time, and as I did not observe that she came out, I conceived an expectation of

seeing the whole body quickly abandon their settlement; but instead of that, I soon observed them gathering closer together without the least signal for departing. Upon this I immediately reflected that either there must be another sovereign, or that the same was returned. I directly commenced a second search, and in a short time, with a most agreeable surprise, found a second, or the same. She strove, by entering farther into the crowd, to escape me; but I re-conducted her, with a great number of the populace, into the hive. And now the melancholy scene began to change to one infinitely more agreeable and pleasant. The bees, missing their queen, began to dislodge and repair to the hive, crowding into it in multitudes, and in the greatest hurry imaginable; and in the space of two or three minutes, the maid had not a single bee about her, neither had she so much as one sting—a small number of which would have quickly stopped her breath." The queen-bee, it may not be out of place to remark, is distinguished from the others by the considerably greater length of body, the upper portion being of a deeper black than that of the workers, while the under surface and the limbs are of a rich tawny colour. The legs are longer, but without hairy brushes at the joints; the proboscis is more slender, and the hinder pair of legs are without the cavity possessed by the others for collecting farina. In the breeding season the body is greatly swollen and elongated. The notable point of the above story is the harmlessness of the bees during the swarming season, when they are intent upon following the queen-bee, provided they are not excited or enraged by being injured or crushed. Many people directly court attack from bees and wasps by the wild state of excitement into which they allow themselves to be thrown by the approach of an insect, and the frantic efforts they make to get at it with a handkerchief, or to drive it off. Much less risk is run if the person will quietly move off, and at anyrate forbear exciting the insect by such means.

Many persons are peculiarly susceptible to the sting of bee, or wasp, or other insect, the part bitten becoming speedily inflamed, much swollen, and painful. Others again are much more tolerant. A single sting on the eyelid, or in its immediate neighbourhood, will, in susceptible persons, soon cause so much swelling that the eye is closed up. Death has resulted in such persons from a single sting. Cases of stinging in the throat have occurred, death arising from suffocation by the great swelling occasioned. Death is usually due, however, rather to the shock of numerous stings and the collapse they produce.

The treatment of such stings is similar to that for much more serious insect stings, snake bites, &c. In the case of the bees and wasps the sting is often broken off and left in the wound. It should be immediately removed with fine tweezers, and then some alkaline remedy is applied to destroy the acid character of the poison introduced. Lime, chalk, baking soda, moistened with water, are all useful and materially diminish the pain. Even loam is useful. But best of all is ammonia water (hartshorn) or aromatic spirit of ammonia freely applied. A popular and very useful remedy is the leaf of the common dock, bruised, the juice being rubbed into the wound, after withdrawing the sting, for ten or fifteen minutes. A poultice of ipecacuanha is believed by some to be an antidote for every kind of poisonous bites. Cold water applications continuously applied for some time will relieve the pain and diminish the swelling. Olive-oil, vinegar, laudanum, are also recommended, or a lotion of a tea-spoonful of sugar of lead dissolved in a tea-cupful of cold water. If the throat is stung the sting should be removed if possible. Fifteen drops of ammonia water, well diluted, may be given to sip, and repeated in a quarter of an hour, ice to suck, warm water and salt with which to gargle the throat, and cloths wrung out of hot vinegar and water are wrapped round the neck. If the swelling threatens suffocation a surgeon would lessen its amount by scarification, while if the shock is great other stimulants are necessary, hot whisky, or brandy and water, along with 20 drops of laudanum, repeated in an hour, if needful, to diminish the pain. In such cases the opening of the windpipe—tracheotomy—might be necessary to permit of breathing.

The Mosquito is another common pest of warm climates. Its bite is inflicted by a long lancet-like organ of six bristles, folded together in a grooved sheath. After the bristles penetrate the skin the blood is drawn by the channel found between them. The treatment is the same as for the sting of the bee or wasp.

The Chigoe (*Pulex penetrans*) (Fig. 370), Chique, Pique, Bicho, or Jigger is very common in the West Indies and tropical America. It attacks the feet, the female burrowing beneath the skin, and forming a little cyst in which it lives until the body is distended with eggs. The small swelling is then of the size of a pea and

of a bluish colour, and it occasions violent itching. It penetrates chiefly under the nails. The cyst can be extracted entire with the point of a needle by those expert at it; but if it is broken and the young escape severe inflammation arises. The means of prevention is constant cleanliness, and the wearing of covering on the feet whether in or out of doors.

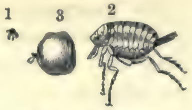

Fig. 370.—Chigoe.

1, male chigoe of the natural size; 2, the same magnified; 3, a female full of eggs, natural size, as taken from a human toe.

Ticks of many varieties abound in the tropics. They bury the head under the skin and suck the blood in that position. When the body is pulled away the head is usually left, and should be extracted with tweezers; nicking the skin with a sharp knife aids the process. The use of very hot water aids their removal, lessening the risk of breaking off the head.

Midges are a common pest, and on some people produce much swelling and painful itching. Whisky is often applied to the skin to relieve the pain, and those whose face readily becomes swollen find much benefit by laying a piece of cloth soaked in the whisky over the skin. An ointment made of 60 drops oil of pennyroyal to one ounce of vaseline, lard, or other simple ointment, smeared on the face is a useful preventive. Equal parts of wood tar and sweet-oil are also used to smear exposed parts. Camphor and lemon juice are also used; and carbolic acid sprinkled freely about a room prevents their attack. But mosquito curtains well arranged are a necessity. Those who camp out use a smouldering fire of green wood, placed where the smoke is blown about the tents, as a prevention to attacks both of midges and mosquitoes.

Bed-bugs (*Cimex lectularius*) are not easy to dislodge when they gain a footing in a wooden bed. One of the best applications is a mixture of three parts petroleum and one hundred parts of water. This is applied to all cracks and crevices of woodwork. Beds should be scalded with boiling water. Fumigation with sulphur is an effectual remedy. Bed-bugs are said not to venture from their corners except in the dark, and that if even a feeble light be kept burning in a room all night they will keep in confinement.

Spiders of various kinds are also very obnoxious. There is the black spider of the northern parts of America, whose bite causes sometimes much pain and inflammation, and the **Tarantula** of the south-west, a large spider capable of inflicting a severe bite, which may be followed by severe shock and inflammation. Such bites are to be treated in the way recommended for the stings of bees, ammonia lotion and a poultice of ipecacuanha specially being recommended.

The Scorpion and Centipede are common in the southern states of America, and in Asia and Africa; and they there attain a large size, the latter often being from five to seven inches long. The scorpion belongs to the spider class; and carries its sting as a hooked claw prolonged from the abdomen. At the base of the claw is the poison gland, a fine channel running to the point. In the latter the offensive weapon is part of the jaws, hooked in form, and perforated with a fine canal for the discharge of the poison. The bites of these animals are often very severe, causing serious inflammation, great depression of vital powers, and much collapse. They are to be treated in the same way as stings of bees and wasps, ammonia and whisky being applied to the part, and stimulants given internally. To remove the poison from the wound small incisions are made and encouraged to bleed, and the wound may be sucked, if no scratch exists on the lips or mouth. The use of cupping glasses after scarification is also recommended.

The Guinea-worm (*Dracunculus* or *Filaria medinensis*) is in one stage a minute animal inhabiting water or moist soil, and common in the East Indies and on the coast of Africa. It attacks those exposed to it owing to bare feet and legs, pierces the skin and then proceeds to develop the worm form in the loose tissue. It is the female only that is known. In this situation it grows to a length varying from one to six feet, of the thickness of vermicelli, and it reaches its maturity, when its body is filled with eggs, in about nine months. Much pain, stiffness, and swelling accompany its growth, and finally a large bleb filled with fluid rises on the skin, usually in summer. When the raised

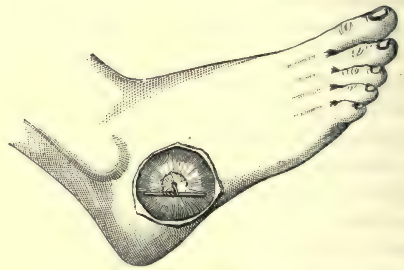

Fig. 371. Mode of Extraction of Guinea-worm.

cuticle has been removed, the head and an inch or more of the body of the worm are seen projecting from the centre of the raw surface. An abscess may be formed, and when it is opened the head of the worm is found. It is removed only gradually by twisting the fine end of the worm round a piece of adhesive plaster, rolled into a quill shape, or round a piece of wood such as a match, and then every day a turn or two is given to the plaster or match, the worm being gradually wound upon it, no violence being used lest the body be torn (Fig. 371). After a more or less prolonged period the tail of the worm is reached, recognized by its hook-like appearance.

Snake-bites.—All snakes and serpents are not venomous, though all are capable of biting. One of the main distinctions between those that are poisonous and those not so is that the poisonous reptile, as a rule, has no ordinary teeth in the upper jaw, but has instead two long curved conical fangs. These fangs, when not in use, may be concealed in folds of the lining membrane, but when the jaw is opened they are erected to strike. Connected with each fang is the poison gland, one of the glands of the mouth, which has undergone special development, and a duct from the gland passes to the fang, which is perforated to the point by a fine channel down which the poison can be discharged, when the animal strikes. Behind these upper jaw-bones the palate bones carry a row of teeth, fitted for seizing and holding or squeezing prey, but not for chewing. In non-poisonous reptiles the poison fangs are not present, but there is a row of teeth in the ordinary position in the upper jaw, and rows of the palatine teeth behind them. Fig. 372 shows the head of a venomous snake —a viper, while Fig. 373 shows the head of the British snake, which is destitute of these fangs, and is therefore harmless. The forked tongue seen protruding from the mouth in each case is not capable of doing harm. It is formed by two muscular cylinders united towards their base but free at their extremities, and used rather as an organ of touch than of taste.

Fig. 372.
Head of Poisonous Snake.

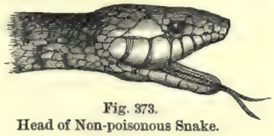

Fig. 373.
Head of Non-poisonous Snake.

Among the non-venomous snakes are the common **ringed snake** of Britain, already mentioned, the **black snake** (*Bascanion constrictor*), and the **pythons** and **boas**, which include the kinds popularly known in America as the **anaconda.** These latter, all belonging to the boa family, include the largest and most powerful animals of the serpent species. Though their bite is harmless they are very destructive, because of their power of winding themselves round the bodies of their victims and crushing them into pulp in their coils, preparatory to swallowing them.

To the venomous serpents belong the **common viper,** occurring in England and Scotland, which inflicts a severe bite, but not commonly deadly except in the case of children and feeble persons, and the American **rattlesnake** (*Crotalus horridus*), which is very deadly. The rattle is due to a series of horny scales, jointed to one another, at the end of the tail, the shaking of which, when the animal throws itself into a coil, makes the noise. The **water viper** or **moccasin** (*Cenchris* or *Ancistrodon piscivorus*), found in swamps in warmer parts of America, the **copperhead** (*Trigonocephalus contortrix*), the **cotton-mouth** (perhaps a variety of the copperhead), and the **harlequin-snake** (*Elaps fulvius*), are all venomous and found in America. In Brazil and Central America is found a poisonous variety, of the same species as the rattlesnake, and called the **jararaca**; in Australia the **tiger-snake** and **death-adder** (*Acanthophis tortor*) are venomous; in Africa the **horned-snake** (*Cerastes cornutus*) and **puff-adder** (*Clotho arietans*) of the Cape of Good Hope, and the **asp** (*Naje haje*) are the best known and most dreaded. In India, where it is calculated 20,000 natives die annually from snake-bite, the chief poisonous serpents are the **cobra,** cobra-di-capello (*Naja tripudians*), the **bungarus** or **rock-serpent, Russell's viper** (*Daboia*), chain-viper or tic polonga of Ceylon, and the *Ophiophagus Elaps.*

The cobra is also called hooded or spectacled snake, because the skin of the neck is very loose, and can be distended to cover the neck like a hood, while the ocelli on the back of the neck produce the spectacled appearance.

Besides those named, poisonous sea-snakes abound in the Indian and Pacific Oceans.

The effects of a snake-bite, as well as those of stings, depend on the amount of poison injected into a wound. This is not the case with poisoned wounds, such as dissection wounds, wounds poisoned by putrefactive material. The poison injected in the case of the snake-bite is not capable of multiplying in the system. It contains an alkaloid, according to some, acting by

chemical activity. If one has been thoroughly bitten, a double wound should be seen, the punctures of the two fangs, half an inch apart. Intense pain and swelling occur at the bitten part, extending up the body. Symptoms of shock quickly come on, giddiness, loss of speech, clammy sweats, dimness of vision, faintness, weakness, sickness and vomiting. Drowsiness, stupor, unconsciousness, and perhaps convulsions occur. Death occurs generally within two hours, but may be more speedy, and death is almost certain if a full dose of poison has been injected by the animal. But if a small dose of the poison has been received, or the venom is inert from some condition of the serpent, recovery may ensue, even after threatening symptoms have been shown.

Treatment of Snake-bite is thus laid down by one of the greatest authorities on Indian poisonous serpents, Sir Joseph Fayrer: "When a person is bitten by a poisonous snake, send at once for the doctor. Pending his arrival, apply a ligature, made of a piece of cord, round the limb or part at or about 2 or 3 inches above the bite. Introduce a piece of stick or other lever between the cord and part, and by twisting tighten the ligature to the utmost. Apply two or three ligatures above the first at intervals of 4 or 6 inches, and tighten them also. After the ligatures have been applied, scarify by cutting across the puncture to the depth of ¼ inch, with a sharp penknife or other cutting instrument, and let the wounds bleed freely, or better still, excise the punctured and poisoned part. Apply either a hot iron or live coal to the bottom of these wounds as quickly as possible, or some carbolic or nitric acid. If the bite be not on a finger or toe, or on a part where the ligature can be applied, raise up the integument with the finger and thumb, and with a sharp penknife cut out a circular piece as big as a finger nail round each puncture, that is, round the points of the finger and thumb, to the depth of ¼ inch. Then apply the hot iron to the bottom of the wounds, and wash the part with solution of permanganate of potash. Give fifteen drops of liquor ammonia, diluted with water, immediately, and repeat it every quarter of an hour, for three or four doses or longer, if symptoms of poisoning appear, or give hot brandy or other spirit, with an equal quantity of water, about an ounce of each for an adult, at the same intervals. Should no symptoms of poisoning come on in half an hour the ligatures should be relaxed, or the part will perish from gangrene. If depression, faintness, nausea, hurried respiration, and exhaustion supervene, the ligature should not be relaxed until the person is recovering, or until the ligatured part is cold and livid.

Another plan lately introduced by M. de Lacerda is not to scarify, excise, and cauterize, &c., but to inject into the site of the bite a 1 per cent filtered solution of permanganate of potash, the object being to follow up and neutralize the poison. If by this method a sufficient quantity of the antidote could be accurately brought into contact with all the virus in the tissues (the mixture of snake poison and solution of permanganate of potash out of the body, when injected under the skin, is quite innocuous) it might prove an effectual remedy; and we are glad to observe that Mr. Richards is zealously prosecuting a series of experiments, with a view to determine the value of the practice.

Sucking the wounds may be beneficial, but as it may be dangerous to the operator it cannot be enjoined as a duty. If, however, it be practised, rinse the mouth thoroughly both before and after the procedure, with the permanganate of potash solution. If symptoms of poisoning set in and increase, if the patient become faint or depressed, unconscious, nauseated, or sick, apply mustard poultices or liquid ammonia on a cloth over the stomach or heart; continue the stimulants, and keep him warm, but do not shut him up in a hot stifling room or small native hut; rather leave him in the fresh air. Do not make him walk about if depressed; nurse him with stimulants, mustard poultices or ammonia, but let him rest. If the person be seen some time after the bite has been inflicted, and indications of poisoning are present, the same measures are to be resorted to, or the new method of M. de Lacerda may be adopted. They are less likely to be successful at this late period of the case, but nothing else can be done. In many cases the prostration is due to fear; the bite may have been that of a harmless or exhausted snake, and persons thus bitten will, of course, rapidly recover under the use of the above measures. If poisoned, but, as is frequently the case, not fatally, these measures are also the most expedient; if severely poisoned, no others are likely to be more efficacious. People should be warned against incantations, popular antidotes, and loss of time in seeking for skilled aid. The remedial means suggested are no doubt severe, and not such as under other circumstances should be intrusted to non-professional persons; but the alternative is so dreadful, that, even at the risk of unskilful treatment, it is

better that the patient should have a chance of recovery."

The two objects of this treatment are, first, to remove the poison before it can get into the circulation, if possible; and second, to maintain the strength of the patient by stimulants till any poison that has gained entrance to the blood is expelled by the ordinary excretory channels. For the latter purpose whisky is much relied on, and is given at frequent intervals, even to the point of symptoms of intoxication beginning to show themselves. Under the circumstances, however, very large quantities can be given without intoxication being induced; but it is needful to observe that that condition is not desired.

Bites of other Animals.—Hydrophobia is the only disease requiring mention as resulting from the bites of dogs, cats, foxes, &c., and it has been discussed on p. 421.

The Poison of Venereal Disease.—There is one disease of this class, due undoubtedly to a special poison, which has been already described elsewhere (p. 422). There are other two affections, occasioned also by the introduction into the body of morbid material, but whether they are as truly the result of specific poisons is not so certain. The one is **soft chancre**, chancroid ulcer, or the soft sore, so called in contradistinction to the hard sore, which is the first step in the production of syphilis; the other is an inflammation of the urinary passage, called **urethritis or gonorrhœa.** The soft chancre is a simple ulcer, with a ragged irregular floor, with an abundant yellow discharge; and the tissues beneath it are not condensed and hardened as in the other variety; but, though they may be puffy and swollen, are of the natural softness and mobility. This ulcer tends to worm its way in every direction under the skin and to produce much destruction of parts. Moreover the matter from the ulcer readily produces other ulcers on the same person. This sore appears first simply as a small red inflamed area, where the poison has penetrated. In two or three days it is a pimple and the skin around it is inflamed. In another day it is a bleb filled with clear fluid, which, however, becomes yellow; and when about the sixth day the pustule bursts, the ulcer is the result. It is capable of invading the tissues in every direction and producing extensive loss of substance. There is often considerable surrounding inflammation and pain. Moreover, some of the matter from the ulcer may be picked up by absorbent vessels and carried to the chain of glands in the groin (*d*, *e*, *f*, Fig. 113, p. 208), leading to the inflammation and suppuration of one or more of the glands. This is called a **bubo**. If it actually comes to matter, and is allowed to take its course and burst, then a large ragged foul sore is produced, pouring out a profuse discharge, and the matter of this ulcer is capable of producing a new one on parts with which it comes into contact, just as the matter of the original sore. It is, if not promptly and vigorously treated, almost certain to spread along the groin, invading one gland after another, till a large irregular ulcer is produced. Even although material is not carried up to the glands of the groin infecting them, a bubo may arise owing merely to the irritation. This is called a **sympathetic bubo.** It is simpler and more easily dealt with than the former, but may end in the formation of an abscess. The indications of the formation of a bubo are redness, heat, pain, and swelling in the groin. When matter forms the swelling becomes soft, and it points, and soon, if not opened, bursts the skin.

The **treatment** of the soft chancre and such complications as may arise ought always to be in the hands of a surgeon. So much mischief may be produced by neglect, and so much destruction of tissue may rapidly occur, that the sooner the case is dealt with by a competent person the better. The first thing one seeks to do is to destroy the poisonous character of the sore. One of the most effectual ways is by means of strong nitric acid. The sore is wiped clean and dry with lint. A piece of lint in a basin of cold water is placed at hand, then a small piece of wood—the end of a wooden match will suit—is dipped into the acid, any hanging drop is removed against the lip of the bottle, and the piece of wood is passed over the whole surface rapidly, and excess is removed by the use of the wet lint. A white film forms immediately over the sore, due to destruction of the surface. In a day or two this falls off, leaving a healthy surface, discharging healthy matter, and showing the red granulations of a healing wound (p. 968). If the whole surface of the sore has not been touched with the acid it will remain discharging infective material and undermining the skin, reinfecting the healthy portion. It is, therefore, needful to make certain that the acid has been applied over the whole surface, the undermined edges of the skin being specially attended to. If in a day or so the sore seems extending in some directions and healing in others, one may conclude

that the application of the acid has not been thorough enough, and it may then be reapplied. Instead of nitric acid carbolic acid might be used.

After the excess of acid has been removed by the wet lint the part should be dried, iodoform should be dusted over it, and a piece of antiseptic cotton lightly fixed upon it. Twice a day, at any rate, the dressing should be removed, the part carefully washed with hot water, dried, and fresh iodoform and dressing reapplied. Carbolic lotion or chloride of zinc lotion might be used instead of the iodoform, or sulpho-carbolate of zinc lotion (see Section IX., p. 910), the strong penetrating smell of iodoform is so unpleasant. If any of these is used a pledget of lint is soaked in it, placed over the sore, covered with oiled silk, then with a larger piece of antiseptic wool and lightly secured with a bandage.

It should be noted that scrupulous care must be exercised in washing the hands after performing such a dressing, and in burning all particles of lint, cotton, &c., that have been used. No towels should be employed, but only pieces of lint, &c., that can readily be burned. All this is to prevent infection of others.

When a bubo is threatened the person should immediately take up a reclining position and keep at perfect rest, since motion only aggravates the pain and swelling. Then cloths, lightly wrung out of iced water, should be placed over the part and renewed every few minutes for half an hour or so on end. After two or three hours' interval this process may be repeated. If the pain and swelling begin to subside, this treatment should be persevered in, the ice, however, never being so long applied continuously as to produce a livid appearance on the part. If, however, the swelling increases and becomes soft, it is clear matter has formed, or is forming, the ice is to be abandoned and warm applications employed. At the very earliest moment the abscess should be opened, for if this be not done the matter may burrow in all directions and effect much destruction. If the abscess be a simple one it is enough to keep it clean by frequent bathing and to apply simple dressings of some antiseptic solution and antiseptic cotton. If, however, it is an abscess produced by absorption of the poison of the original sore, it will, like it, exhibit highly destructive tendencies, and will require to be treated on the same lines as the original chancre.

Throughout all this treatment the person should take light opening medicines of the saline kind (p. 862). should have a plain but wholesome and nourishing diet, and should avoid all spirituous liquors. Complete rest is almost a necessity.

Urethritis or Gonorrhœa is an inflammation of the urinary passage, which may be occasioned by mechanical or chemical irritation, the passing of a catheter or stone, by contact with discharges of a perfectly innocent character, such as that of leucorrhœa (the whites), but which is most commonly due to impurity. But the fact that it may arise in a perfectly innocent way must never be overlooked. In cases due to contagion the first symptoms occur in four or five days, though they may arise sooner or later. They consist in a feeling of itching at the orifice of the canal, a feeling of heat or slight scalding in passing water, a slight thin discharge, and some degree of redness and pouting at the opening of the canal. Within twenty-four or forty-eight hours acute inflammation has developed, the redness and swelling are much increased, the scalding is great, the discharge is copious and white or yellowish white, and there may be frequent desire to pass water, only small quantities coming with difficulty and with much pain. Painful erections (**Chordee**) occur specially during the night. This condition of affairs lasts for several days, or for fully a week, and then the symptoms begin to abate. The pain, &c., diminishes and disappears, and the discharge becomes thin and watery and scanty, and may speedily cease. A thin and scanty discharge may, however, persist for a long period—termed a **Gleet**. There are numerous complications which may occur. Inflammation may extend to the testicle or bladder, and very commonly to one of the glands of the groin, ending in a bubo (see p. 987), which, however, is more easily subdued than that due to soft chancre. Two other complications of gonorrhœa are gonorrhœal rheumatism and an inflammation of the eyes, exactly resembling that described on p. 458 as purulent inflammation of the eyes of the newly born. The treatment of gonorrhœa to be successful depends upon so many details, if it is speedily to effect the cure of the inflammation and prevent it becoming chronic, that it is hardly possible for it to be treated successfully except by a skilled person. The general lines of treatment may, however, be indicated. First of all physical exertion should be avoided, absolutely if possible; the bowels should be unloaded by a brisk saline medicine, such as salts or seidlitz-powder; the diet should consist of skimmed milk as largely as may be, at any rate all fat, highly seasoned dishes, pastries,

pepper, acid substances and fruits being carefully refused, and very specially all alcoholic drinks whatever being denied. Abundance of soda or potash water, apollinaris, or seltzer, may be drunk alone or with milk, as well as ordinary water. These dilute the urine and diminish its irritating characters. To still further diminish the acidity of the urine, to increase the quantity of water passed in order to flush the canal, and to relieve pain, the following mixture is taken in table-spoonful doses every two hours:—

Bromide of potassium,...............	160 grains.
Acetate of potassium, ...	4 drachms.
Infusion of pareira brava, or infusion of buchu,.....................	8 ounces.

Mix.

If the pain and chordee are great, 4 drops of tincture of belladonna may be added to each alternate dose. The part should be kept perfectly clean, but not enveloped in a mass of material, a thin layer of absorbent cotton only being used to absorb the discharge, and fixed by being lightly rolled round the point of the organ and secured by the foreskin being drawn forwards over it. It must be frequently renewed. If the chordee be severe, full doses of bromide of potassium—30 grains in each dose—should be given several times during the day, and along with 5 to 8 drops of tincture of belladonna at bed-time. A morphia suppository ($\frac{1}{2}$ grain) may be passed up into the bowel at bed-time. If so, however, care must be taken to secure free movement of the bowels by a seidlitz-powder early next morning. In many cases the symptoms subside without further treatment. Should they not disappear, but the disease pass through all its stages, injections need to be resorted to, but they are not to be employed during the inflammatory process, but only after the inflammatory symptoms have declined, after the first eight or ten days. When this stage is reached, the simplest injection is that of sulphate of zinc, 2 grains to each ounce. It is at this stage also that, for the first mixture, one containing cubebs and copaiba is substituted. Perhaps the simplest form is that of capsules containing 20 drops each of oil of cubebs and copaiba, of which two to four are taken three or four times daily, or instead 10 drops of sandal-wood oil on a piece of sugar three or four times daily, or 20 drops of copaiba with 20 of liquor potassæ and an ounce and a half of water may be taken thrice daily. Such treatment ought to be sufficient to effect a cure; but it must be remembered that a modified form of the inflammation may readily recur with a slight exciting cause, and great care and moderation in eating, drinking, and in other habits will be necessary to confirm the cure. The manner of giving the injection is of the utmost importance, since unless the injection fluid be brought into contact with all of the inflamed membrane of the canal no benefit can be expected. The patient should have a glass syringe, capable of holding one ounce. It should be provided with a bulbous end. When the syringe has been completely filled with the injection fluid and all air expelled, the bulbous end is introduced into the canal, the organ being held upright with the left fore-finger and thumb. The mouth of the canal is pressed against the syringe to prevent any fluid escaping; and the piston of the syringe is slowly pressed down till the canal is full. When the syringe is withdrawn the person must compress the mouth of the canal with finger and thumb for two or three minutes, to retain the fluid. When the person lets go, the fluid is immediately ejected by the elasticity of the canal. Before the injection is given the patient should pass water to wash any matter out of the canal, and prevent it being driven up into the bladder by the injection. Instead of the sulphate of zinc, sulpho-carbolate of zinc may be used in solution, 1 grain to each ounce of water, or Goulard's water. Chronic forms of the disease it is needless to consider here, nor yet cases of gonorrhœal rheumatism or ophthalmia, which must have expert treatment. Complete rest and the use of saline opening medicines and the application of iced cloths, as suggested on p. 988, will often arrest a threatened bubo or inflammation of the testicle. In the latter case a suspensory bandage to relieve the parts of dragging is essential.

Section III.

SHOCK OR COLLAPSE AND SYNCOPE OR FAINTING AND INSENSIBILITY: THEIR TREATMENT. THE TEMPORARY TREATMENT OF FRACTURES. THE CARRIAGE OF INJURED PERSONS.

Shock or Collapse:

SHOCK OR COLLAPSE, AND SYNCOPE: THEIR TREATMENT.

Shock is a state of depression of all the vital powers, following upon some injury or marked mental or emotional impression. The degree and duration of shock are very various, being dependent not only upon the severity of the injury or impression, but also upon the vigour and susceptibility to nervous impressions of the individual. Thus a sudden injury may produce such a profound and paralysing influence upon all the vital powers that death may occur almost immediately or after a brief period. For example, a sudden blow on the pit of the stomach may cause death, due to shock, and after an extensive burn death may occur from collapse in spite of efforts to produce a rally by means of stimulants, &c. On the other hand, an individual may suffer from slight and passing shock, owing, for example, to the receipt of sudden tidings, either joyful or painful, or owing to some slight injury or sudden pain. To take this last instance first, most people know what are its signs—the sudden blanching of the face, the appearance of confusion, the tottering gait, the clutching at a support or sinking into a chair, the trembling that seizes the whole body, the coldness of the hands, indeed of the whole body, the cold clammy sweat that bathes the surface, the sickness, perhaps, and faintness. After a few minutes of anxiety, there is often a prolonged sigh as if some heavy load were being removed, and the colour begins to return; the person begins to rouse himself; and it may be that the momentary depression passes into a brief period of reaction, during which the person's face becomes suffused with a bright flush, and the skin becomes warm and moist. When the shock is more severe, the pallor of the skin remains; the hands and feet are specially cold; the pulse is feeble but quick, sometimes scarcely perceptible at the wrist; the breathing is slow, shallow, and sighing; and the person, though conscious, lies still, with dull eyes, but a strained look upon the face, replies weakly and with effort to any questions, and is, as a rule, entirely indisposed to make any effort either in moving or speaking, while there are indistinctness of vision and confusion of thought. Vomiting may occur and the patient begin to recover, as evidenced by the strengthening of the pulse, the increase in the breathing, the return of blood to the skin and its consequent warmth and moisture. During the period of shock the temperature is invariably below the normal, from a half degree to one and a half or more, and the depression of the temperature is a very good guide to the degree of the shock. If the depression increases, instead of diminishing, all these symptoms become aggravated, the prostration is more marked, weak quick pulse,

feeble imperceptible breathing, and anxious only semi-conscious look upon the countenance; while the pupils are usually dilated, and motions are passed involuntarily from the bowels. Spasmodic muscular twitchings often occur. If, however, the shock is passing off, there are gradual improvement of pulse and breathing, gradual restoration of colour and animation to the face, and gradual restoration of warmth to the surface. The state of depression over, the person passes into a state of **reaction**, with full bounding pulse, quickened breathing, flushed and moist skin, and elevated temperature. This reaction stage usually corresponds, though not always, in duration and degree with the preceding depression. The more severe and prolonged the collapse has been, the more pronounced will be the after reaction. Commonly, however, its signs do not pass much beyond the activity of the normal healthy standard. But after injury or operation it may be so well marked as to become an actually feverish condition; thirst, loss of appetite, foul tongue, constipation, scanty high-coloured urine, excitement and loss of sleep, indicating general disturbance of the functions of the various organs. When reaction goes to this extent, the term **traumatic fever** is applied to it.

In some cases of shock, the patient, instead of being motionless and listless, is restless and excited, tossing about in bed, throwing the arms from side to side and moving the head, in an apparent state of great mental distress. At the same time the other signs of lowered vital powers are to be found, namely pallor, weak pulse, and feeble breathing.

The state of collapse which has been described is usually most severe after injuries involving considerable injury to the tissues or covering an extensive surface. Thus in extensive burns, it is the collapse that is dreaded to begin with rather than the actual injury itself; and it is a most marked feature of injuries accompanied by considerable bruising or crushing of parts, or injuries to bones or joints. The restless form is witnessed when there has been considerable loss of blood, or where there is much pain. Usually, however, in the state of collapse the sensations are much blunted and the patient is not acutely sensible to pain, even sharp pain, but only vaguely conscious of it.

A person may remain in a state of shock for a variable time, from a few minutes to several hours, and this depends not only upon the severity of the injury but also upon the state of the person. For example even trifling accidents produce severe symptoms of shock in persons subject to kidney disease, while women and children and persons of a nervous temperament have rapid and sharp reaction, followed by speedy recovery.

The causes of these symptoms that have been described are no doubt to be referred to the nervous system. In the case of death following a blow on the stomach the fatal result is due to the powerful impression made upon a large mass of nervous substance, called the solar plexus, and connected with the sympathetic system of nerves (see p. 98), which is situated behind the stomach. It is the duty of this system of nerves to preside over the animal functions, the distribution of blood, the action of the heart, the work of the digestive organs, and so on; and any profound impression upon these nerves necessarily affects in a most marked way all these processes. When one, then, considers that it is the effect produced on the nervous system which results in the production of the symptoms that have been described, one can understand how such different things as a sudden joyful surprise, a piece of bad news, a sudden fright, an unlooked-for appearance, or a fall or other injury, may all produce similar effects. The feeble heart, the faint breathing, the cold skin, the vacant mind, the lessened sensibility to pain, are all evidences of unequal and irregular distribution of blood and faint stimulation of the heart, the result of weakened or semi-paralysed nervous influence.

Syncope is a condition akin to shock in its nature and cause. It is sudden and profound and caused by arrest of the heart's action. It may occur because of sudden emotion or fright, or because of pain, or loss of blood. It has been already described on p. 243.

The Treatment of Shock.—In the very slight cases of shock little or no treatment is required. The person should be made to sit down or recline, and the application of smelling-salts to the nostrils, the administration of a tea-spoonful of aromatic spirits of ammonia (sal volatile) in water, or any hot drink, will usually be sufficient. This is practically the same treatment as has been already described for fainting on p. 243. In the case of severe shock, however, much more is necessary. A consideration of the real nature of the attack will clearly show that the two chief objects to be sought in treatment are the restoration of the warmth of the body and of the activity of the circulation. Both of these objects are obtained by the same treatment. The person is to be laid on a bed or couch and the clothes are

to be quickly removed, the usual night garments being substituted. Hot-water bottles should be placed at the feet, or hot bricks wrapped up in flannel. It is needful to warn against placing a bottle filled with boiling water against the patient's body unprotected from excessive heat. For, in the state of diminished sensibility of the patient, actual burning of the skin might occur without the person experiencing pain. A very severe case of this sort came once under the author's treatment. If the coldness of the body is extreme and the prostration great, the patient may be wholly wrapped in warm blankets, and hot-water bottles placed outside the blankets to maintain their warmth. In such extreme cases, also, flannels wrung out of hot mustard and water (a table-spoonful of mustard to a pint of hot water) should be placed over the chest and belly, and specially over the heart, and these may be frequently renewed. Or a mustard poultice may be applied, or a cloth sprinkled with turpentine and then covered over with a thick flannel pad wrung out of hot water. Meanwhile, any assistants may be occupied rubbing the limbs from their extremity upwards. This should be done without exposing the parts to further cold. In the next place stimulants are to be given by the mouth, if the person can swallow. Whisky or brandy in hot water is undoubtedly the best. Two or three tea-spoonfuls of the spirit in half a wine-glassful of hot water may be given at once, and this may be repeated in twenty minutes or half an hour, if needful. It may be repeated at brief intervals several times, the pulse being taken as an indication of its need; but excitable people are apt to administer large quantities in their terrified zeal; and this must be guarded against. Strong hot coffee or tea is also useful if an alcoholic stimulant be not at hand. Instead of any of these, ammonia, either in the form of the weak spirit of hartshorn (10 to 15 drops in water) or in the form of the aromatic spirit (half to one tea-spoonful in water), may be given by the mouth and frequently repeated. Small quantities of hot beef-tea—a wine-glassful at a time—are also useful, frequently repeated. If the person cannot swallow, the stimulant—whether of whisky and water or milk, brandy and water or milk, or wine and water, or ammonia and water—should be injected into the bowel. Severe cases of shock, and the shock of snake bite, have been treated successfully by the injection *into a vein* of 10 drops of the spirit of hartshorn in 1 or 2 ounces of warm water. This could only be undertaken by a medical man, but the same quantities could be injected into the bowel without risk by anyone. Ether—sulphuric ether—is often employed to produce a rally in profound prostration after injury or loss of blood—10 to 30 drops may be injected under the skin by means of the hypodermic syringe. It acts with great rapidity. All these measures are not necessary except in most extreme cases. In ordinary cases, in which the circulation is restored in from half an hour to two or three hours, the warmth to the body, friction, and the hot stimulant are quite sufficient. Provided the pulse is gradually improving it is a mistake to be too officious. Someone requires to "stand by," and give occasionally another small dose of the stimulant, for in such cases the patient is quite conscious and able to swallow. By being too energetic one is apt to encourage an excessive reaction and some amount of fever. Should such undue reaction occur iced cloths may be applied to the head, stimulants are to be stopped, diet is to be kept low, and, if necessary, a dose of purgative medicine may be given, 5 grains of calomel followed by castor-oil or a dessert-spoonful of some saline medicine such as granular effervescing citrate of magnesia.

It is to be remembered that sometimes, after a patient has begun to rally, a relapse occurs. Therefore he is to be watched carefully. As soon as the pulse, breathing, and colour are improved, stimulants should be given less frequently, but watchfulness exercised so that on the slightest appearance of renewed depression an additional quantity might be given.

The treatment of shock accompanied by restlessness is to be conducted on the same lines, for the restlessness and excitement are indicative of great weakness to be met by stimulating drinks and nourishment.

Insensibility or **Unconsciousness** may arise from many causes, from concussion of the brain (p. 104) as the result of a fall or a blow, from shock (p. 990), from an epileptic (p. 123) or apoplectic (p. 103) fit, from fainting (p. 243), from poisoning by alcohol (p.1024) or opium (p.1025). The symptoms of these conditions have been already described in the paragraphs already referred to and the appropriate treatment stated. Great and sudden loss of blood will also cause deep unconsciousness. The surroundings will often indicate clearly the nature of the case. It may be evident from the situation and position of the body that the person has fallen from a height; the presence of wounds will assist the formation of an opinion. If the unconsciousness is due to loss of blood from a wound, or a rup-

tured varicose vein, this will usually be evident. The features of apoplexy (see p. 103) are easily distinguished from shock or fainting.

In all cases lay the patient on his back, the head slightly supported; have him under cover; remove all tight clothing; arrest any bleeding; restore and maintain the heat of the body by friction and warm applications. In cases of shock, fainting, loss of blood, stimulants are necessary. But in apoplectic seizures, concussion of the brain, and epilepsy, efforts to restore consciousness and the use of stimulants are hurtful. Alcohol and opium poisoning are spoken of elsewhere.

THE TEMPORARY TREATMENT OF FRACTURES.

Fractures have been considered at length on p. 35 and the following pages, and the causes, varieties, symptoms, and treatment of them have been detailed at length. In this part, devoted to accidents and emergencies, however, it is thought advisable to make a brief summary of the means by which the fact that a bone has been broken may be determined quickly in the cricket, football, or hunting field, and to explain how, without any of the special appliances described in the pages referred to, such accidents may be temporarily treated, so that additional injury may not be inflicted before surgical aid arrives, or in course of conveying the person within reach of it.

Such information is of the utmost value to all engaged in out-door sports and to many others besides, and ought to be in the possession of everyone. Such an injury may be readily sustained, and often is so, by even a simple jump from a style, by a fall, by a kick, by a fall from a horse. In the most of these cases the injury is comparatively simple, the damage done is not extensive, and if the broken bone were, then and there, properly secured till it could be treated by a surgeon, comparatively rapid recovery would be made. But very often much more extensive damage is inflicted than that due to the original accident, because of the want of knowledge of how to handle the limb on the part of those who come to the aid of the injured man. Too often a patient, who has suffered a break of one of the bones of the lower leg, is encouraged to make repeated attempts at walking, supported on each side, or is roughly and unskilfully carried to some shelter, the injured limb being permitted to dangle and twist, to the grievous injury of the soft parts. A simple fracture is often thus converted into a compound one by the ends of the broken bone being thrust through the soft parts, or by its movement vessels are torn and nerves injured, and a simple injury converted into one of great extent and gravity, while inflammation is excited and much pain inflicted. All this a little knowledge would render impossible. No harm is done if a limb is supposed to be broken, the bone of which has really suffered no such injury, and if under the mistaken notion the temporary treatment for a broken bone be adopted, while great injury and suffering may be the result of mistaking a fracture for a dislocation or of failure to think of the possibility of fracture at all.

The General Signs of Fracture will be briefly stated. They are noted in detail on p. 36. The first is immediate disablement. If the leg be broken the person falls to the ground, and if he attempts to rise it is only to fall again. The broken arm falls by the side. When the collar-bone is broken the shoulder drops and cannot be raised by the person himself. Then the limb is more easily moved than its fellow; it bends at the break, unless in the case of the lower leg or forearm, when only one of the two bones is broken and the other acts as a splint. On pressing with the thumbs at the seat of injury the two ends of the bone yield and a grating feeling may be experienced. Usually deformity is produced by the muscles acting on one or other of the parts of the bone; thus, in the case of the thigh, the limb is shortened and turned out, and so on.

We shall notice the more common fractures separately and indicate how they are to be temporarily adjusted, the directions given being in every case fully illustrated in Plate XV.

Temporary Treatment of Fractured Collar-bone.—In this case the dropped shoulder, which the person cannot raise by action of the muscles, the ends of the broken bone projecting under the skin at the upper part of the chest, and their mobility and grating, indicate the nature of the accident. A firm pad is to be made, which can be improvised of pocket handkerchiefs, a soft cap, a waistcoat rolled up, or for that matter a bundle of hay rolled up in a handkerchief; and it is to be placed well up into the arm-pit to raise the shoulder. If the person applying the pad will grasp the upper arm, high up, with the left hand, and raise the shoulder, bracing it back at the same time, and then push up the pad, the replacement will be effected. The forearm is to be bent and folded over the chest, and kept in that position till a bandage is passed round the chest—a triangular bandage,

or a handkerchief or a neckerchief, or if nothing else is to be had a belt or a brace—to fix it there. Lastly the arm is to be supported in a large sling, the elbow being well held up. (See fig. in Plate XV.)

Temporary Treatment of Broken Upper Arm.—Here the position in which the person holds the arm is significant. He supports the elbow by the hand of the uninjured side, holding it close to his side. The mobility of the upper arm, the shortening produced, the irregular hollow felt on passing the hand down from the shoulder, whose roundness is maintained, all indicate at once what is wrong. The ragged ends may readily be felt even through a coat sleeve. It is not necessary to remove any clothing, in fact inadvisable, for every disturbance except by a skilled person is apt to be hurtful. Let the forearm be bent and held over the chest, let the person assisting put a narrow sling round the neck, supporting the wrist but *not the elbow* (see Plate XV). That done, let him look for something to act as a splint. A piece of paling may suit, or a pair of hunting whips (see Plate XV.), or a walking-stick broken in two. Something should be wrapped round the temporary splints to protect the arm from undue pressure. One piece is to be placed on the front and another on the outer side, and inside it will be well to place a pad, which a folded waistcoat will readily supply. Then let something to fix them with be looked for, handkerchiefs, neckties, braces. In the case of the hunting whips, the whip ends might do in the absence of everything else. Let all be got ready to save unnecessary handling of the arm. Then place the splints in position on the front and outer side of the arm and the pad on the inner side, *take care that the pad does not press too far up into the arm-pit to hinder the circulation*, and place the straps ready to be tightened. Then let one person firmly grasp the arm above the elbow and pull gently but steadily downwards. The displaced ends of bone will readily be brought opposite one another, and then the straps are firmly secured to keep them so. If only one person be present beside the injured man, it will be necessary for him to apply the splints and partially tighten the bandages before pulling on the limb, in order that when the arm is pulled down he may be able to complete the tightening with one hand, while he holds the arm in extension with the other. By having the sling on previously his task will be easier. If two persons are present to assist, one will keep the fragments together while the other adjusts the splints and bandages.

Temporary Treatment of Broken Forearm.—If only one of the two bones of the forearm (see Plate I.) be broken, temporary treatment is very simple. It is only necessary to place the arm in a broad sling, without disturbing any clothing or applying any splint, for the unbroken bone acts as a splint. That such a break has occurred is discovered by passing the thumbs one after the other along first one side of the forearm and then the other. When the break is reached, pain is complained of by the person, the bones are perceived to yield, and grating is felt by the person assisting. If both bones be broken, the forearm yields completely at the break and deformity is produced. Here again two pieces of paling, the two halves of a broken walking-stick, &c., are to be procured. If such a narrow piece of wood as a stick affords is all that is to be had, it is better to roll it up in a waistcoat or anything else which will give it some breadth and prevent it pressing unduly on one part of the forearm only. If the injured person has his coat on, it should not be removed; if he happens to be at the time coatless some soft padding *must* be interposed between the arm and the extemporized splints. Bend the forearm and carry it across the chest, thumb directed upwards. Apply the padded splints so that one lies along the front of the forearm, projecting out beyond the elbow behind, *not pressing into the elbow*, while the other lies along the outer side, and secure with one or two straps, which handkerchiefs, neck-ties, garters, &c., will provide. If both bones are broken it is necessary before applying the splints to grasp the hand, and, the elbow being fixed, gently to pull on it to reduce displacement and bring the broken ends opposite one another, in which position the forearm must be fixed. This is not necessary if only one bone is broken, since the sound bone prevents displacement as a rule. Then support the forearm in a sling, the broad sling will be best though the narrow one is represented in Plate XV.

Temporary Treatment of Broken Thigh-bone.—This accident is recognized by the fact that the person cannot use the limb, which is shortened and turned outwards, so that as the person lies on the ground the heel of the uninjured limb rests on the ground while the foot of the broken leg lies on its *outer side*. It is quite unnecessary to remove any clothing, to cut up the trousers, or disturb the clothing in any way. Let the foot of the injured leg be taken by one person, the heel resting in the palm of the left hand and the other hand over the back of the

boot, and let that person gently pull on the foot, turning it into its correct position, so that the heel is directed downwards and the toes upwards; let him bring it alongside its fellow, pulling on it so that the two limbs are of the same length. Meanwhile let another make a pad by rolling up a jacket lengthways, or other suitable material, and place it between the two thighs, extending pretty well up, and down beyond the knee at all events. Then let a splint be found. If only one person is present to assist the injured man, he may insert the pad between the thighs then draw on the foot, and tie both limbs together at the ankle by means of a handkerchief, thereafter going to find a splint. The splint must be long enough to reach nearly up to the arm-pit and down to project beyond the feet. Again a piece of wood torn from a paling might suit. In Plate XV., one figure shows how a rifle might be used, the stock resting up near the arm-pit and the barrel passing down the leg. Let it be noted that the barrel should not be allowed to rest on the ground but should pass *along the middle of the leg*. In the case of the rifle or anything so thin, a pad to surround it and so increase its breadth would be a great advantage. The extemporized splint being applied is to be fixed by several triangular bandages, handkerchiefs, or the like, which are to secure, not only the splint on the outside but also the pad on the inside. Finally a strap is to be passed round the body and the upper end of the splint, and another binds both legs together. Thus one leg acts as a splint on the inner side of the other.

After this has been done, as the person will be compelled to lie flat on the ground till means are provided for his removal, those assisting him should see that he is protected as far as possible from damp on the ground by coats, &c., gently passed under him, or he may at once be carried to drier ground if four persons be present, by the method described in the section dealing with stretchers. Three persons kneel down on the left knee on one side of him, one at the head and shoulders, another opposite the hips, a third at the lower legs, while the fourth kneels down on the other side, opposite the middle of the three. All four insinuate their arms under him and all acting together rise as one man, and slowly carry him off. In laying him down again they must be careful again all to act together.

Temporary Treatment of Broken Lower Leg.—The treatment of this accident is quite similar to that of broken forearm and is usually easy, since commonly only one of the two bones of the lower leg is broken, though, of course, both may suffer. In the case of only one being broken, though the person cannot walk or support himself on that leg, there is no displacement, the sound bone acting as a splint. But on passing the fingers along the outer and then the inner side of the leg, a place is reached where pain is complained of, the bones are found to yield and grating is felt. Again it is quite unnecessary to cut up the trousers or remove any part of the clothing. A splint is wanted for the outside of the limb, and, if it can be obtained, for the inside also. Plate XV. shows how two bayonets might be used, or the scabbard of a short sword. In the case of the bayonets it would be necessary to protect the leg from their sharp edges by enveloping them in some thick material which would act as a pad. Whenever possible the extemporized splint should be made to project beyond the foot and should be broad enough there to prevent the foot moving from side to side. Plate XV. shows a cricket bat applied for such a purpose. The splints being padded and applied, one outside and the other inside, they are to be secured by three fastenings at least. If only one splint is available place it outside and put a pad inside. It will be an additional protection to the injured limb, if the two legs be then bound together near the ankles and knees.

Temporary Treatment of Broken Ribs.—The danger of a broken rib or of broken ribs is that, in the carriage of the person, or in his own walking for help, the movement causes one of the broken ends to puncture the lung or do other similar damage. This is the more likely to happen the farther round towards the back the fracture happens to be. Short difficult breathing accompanied by pain, following a fall or blow or squeeze, should lead one to suspect this accident. The person usually carries himself also in a particular way, leaning over to the injured side, and keeping his arm close against it to restrain movement. This is the object of temporary treatment, and is quickly applied by passing a stout *broad* bandage round the chest and fixing it firmly. A shawl might be folded along its length to an appropriate amount, and wound firmly round the body for this purpose, being fixed by pins.

Temporary Treatment of Broken Lower Jaw may be applied by means of an ordinary handkerchief of sufficient length by tearing it into a four-tailed bandage (p. 959). It is torn down the middle from each end to within 3

inches of the centre. The centre is placed over the chin, the lower tails carried up the side of the head and tied on the top and the upper ones to the back of the head, being tied there. Refer to p. 959.

THE CARRIAGE OF INJURED PERSONS.

Of equal importance with the appropriate temporary treatment of injured persons, specially such as have had the misfortune to get a bone broken, is their skilful conveyance to shelter or assistance. Fractures can hardly be put up, however skilfully, so as to render it difficult to do serious injury in transporting the person from one place to another, and any simple means which will lessen the chances of further harm is worth noting. Two persons alone may carry an injured man for a considerable distance without any appliance at all, if he can assume a sitting posture, by forming a two, three, or four handed seat.

A Two-handed Seat is formed by the two carriers standing in line, making a quarter turn towards one another, and locking their hands together by the fingers, palms upwards, the right hand of the right-hand man locking with the left hand of the left-hand man, the other hand of each resting on the shoulder of the other (see fig. 3, Plate XIV.). The locked hands form the seat and support the patient under the thigh-bones a little above the knees, while the other arms support the patient's back. The patient may be able to assist by putting an arm round the shoulder of each bearer.

A Three-handed Seat is formed by the carrier on the right grasping his left forearm above the wrist with the right hand. He then grasps the left forearm of the left-hand bearer, whose left hand grasps the right wrist of his neighbour (fig. 4, Plate XIV.). The left-hand bearer's free right hand is laid on his neighbour's shoulder. The joined arms thus form a triangular seat, and the left-hand bearer's right arm supports the patient's back.

A Four-handed Seat is used when the patient is able to support himself in the sitting position by placing his arms round his bearers' shoulders. Each bearer grasps his own right forearm, near the wrist, with his left hand, and with his free hand grasps his neighbour's left forearm (fig. 5, Plate XIV.). This is called a "Queen's Chair."

Chairs.—A person who may be carried in a sitting posture may be transported in a chair, a high-backed chair if his head and shoulders need support, or an ordinary chair, if he can maintain his sitting posture unaided by a support to his back. A rocking-chair may be utilized for the purpose by passing two stout long sticks, fully longer than broomsticks, under the chair, one on each side, and tying them. The staves should slope downwards from back to front, passing close under the seat at the back and being tied at the junction of the seat and the uprights of the back, and passing *under* the lower round in front, and securing each at the junction of the round and the front upright of its own side. A bearer in front and one behind, standing between the trams thus formed, will easily carry the chair, as the old-fashioned sedan-chair used to be carried. A person with broken ribs should thus be carried in the sitting position, or by a two or three handed seat.

School Forms, Settees, Garden Seats, &c., may be utilized for those who must be transported lying at full length, as in cases of broken thigh-bone, as illustrated in fig. 2, Plate XIV. Such a seat could be carried by hand by four bearers, if a stout stave were passed under the seat at each end in a direction across its length, so that it projected at each side.

Rifle and Blanket Stretcher.—A stretcher may be improvised by means of two rifles and a blanket as shown in fig. 1, Plate XIV. The rug or blanket is fully unrolled. Under each of the two sides a rifle is placed, and the rug is firmly rolled in round the rifle, till the space between the two rifles is reduced to 20 inches. An improvised stretcher may be made of a blanket and rug and four stout poles; rake handles would be suitable. Two long poles are placed on the ground parallel to one another, 18 to 20 inches apart. Near their ends they are crossed by two of shorter length. The poles are firmly tied with whip-cord where they cross one another. The blanket, rug, or sheet is then fastened on, specially well down the sides and at the angles where the poles cross.

Stretchers and Stretcher Drill are considered in detail in a succeeding section.

Plate XIV. fig. 6 shows how by means of a bath towel an injured man, who is able to support himself in a sitting posture, may be carried up a stair with comparative ease.

When it is necessary for one man to carry another, he will do so most easily by placing himself on his patient's right side and lifting him so high that the upper part of the patient's body leans over his left shoulder, the bearer's

FIRST-AID IN ACCIDENTS.

I. This illustrates the application of splints for first-aid in a case of fracture of the lower right leg. An outer and inner splint have been applied and fixed by bandages, knotted on the outside. The legs have then been bandaged together, by one bandage passing over the ankles and another below the knees.

The plate also shows four men of a stretcher squad, kneeling on the left knee, lifting the patient, preparatory to placing the stretcher under him.

II. In this plate an injured man is shown with a triangular bandage applied over the head, the shoulder bandaged by a triangular bandage, and the wrist supported in a sling.

He is being carried by a two-handed seat.

Plate XVa.

I. First-aid in fracture of Lower Leg.

II. Injured Head and Shoulder, patient being carried by a two-handed seat.

left arm passing round his patient's back under his arms, and his right under his legs just above the knees. Captain E. M. Shaw, of the London Metropolitan Fire Brigade, has described another method. First turn the person face downwards, the helper standing in line with the patient and in front of his head. Let the helper then raise the person by taking hold close under his arm-pits, as high as he can, till the body rests on one of the knees. The bearer then stoops, places his arms round the patient's waist and lifts him to an upright position. Again stooping, the bearer passes one arm between the legs and round one of them, grasping with the other hand one of the patient's wrists. The person's body then falls over the helper's shoulder, and he rises with him in this position. The patient's arms are hanging over the helper's back, so that to grasp one of his wrists the arm has to be caught from behind and pulled forward under the bearer's arm. The patient is thus fixed securely on the bearer's shoulder, the hold on the leg prevents him falling backwards, and that on the wrist from slipping down.

ACCIDENTS BY FIRE: THE EXTINCTION OF FLAMES.

There is a very large amount of injury to person and property due to fire accidents, which, at the outset, were of a very insignificant and minor character. Of course, in a sense, all fires, however gigantic their ultimate proportions, are absolutely insignificant in their beginnings, just as the electric flash that fires a hundred-ton gun, or discharges a torpedo is in itself insignificant. The great fire which laid Chicago in ruins is a case in point; and the most recent illustration is furnished by the fire at a charity bazaar in Paris in this year (1897), which was due to a trifling accident with an ether lamp, and which would have done no injury to anyone but for the fact that it was surrounded by light gauzy inflammable stuff. Though the electric flash and such a lamp accident are in themselves insignificant, the surroundings, in which they occur, render their results uncontrollable from the beginning. It is not, therefore, this wide application that is meant when it is said that a very large amount of injury is done by fire accidents of very little moment at the outset. The reference is to a large class of fire accidents quite controllable at the beginning, if only there be someone in the neighbourhood who knows what to do, and is prompt in the doing of it, but which, because of the absence of knowledge and promptitude, become in a few seconds uncontrollable and disastrous. Take, for instance, the case of a pot of inflammable material, like sugar, boiling over, or like the mixture of rosin and turpentine melting over a fire to produce the preparation known to druggists as Venice turpentine. Take the case of an overturned paraffin lamp, or a window curtain set on fire by a gas bracket, or a person's clothing set on fire. In the large majority of these cases the fire can be extinguished speedily and with little damage, if instantly and properly dealt with. But too often the person presiding over the melting pot, or whose carelessness has set the curtain on fire, or overturned the lamp, loses presence of mind and rushes away to get help, and the

delay, however brief, is fatal. Still more, if a woman's clothes have caught fire, is she likely in her distraction to rush about fanning the flames, when a moment's self-possession would save her. How to deal with such minor accidents should be part of the teaching of the young, just as the girl of twelve years is not now deemed too young to be taught, as part of her swimming lessons, the rescue of those in danger of drowning.

Fire cannot live without air. The process of burning is the process of rapid union of something with the oxygen of the air. If the air be cut off the fire must go out, will go out of itself. Anything which hinders the supply of air will limit the fire, and just because the union must be rapid for the production of flame the hindrance need not be complete for the extinction of the flame to be accomplished.

In the next place flame ascends. It extends more rapidly in the vertical than in the horizontal direction. A hanging curtain, therefore, will be speedily enveloped in flames above the part first set on fire, while the flame will only creep slowly along the same curtain lying on the ground. Similarly if a person's clothing has been set on fire, the flames will speedily reach the upper part of the body so long as the person remains erect, but will spread with comparative slowness if the person gets flat on the ground. Moreover, if a person whose clothes have been set on fire rushes distractedly about, she is taking the most effective means of feeding the flames with fresh supplies of air and destroying her chances of escape.

These are the two principles on which the kind of accidents now being referred to are to be dealt with. How are the principles carried into practical effect?

Let us deal, in the first place, with such accidents as an overturned lighted lamp, a pot of inflammable stuff boiling over, a burning curtain. The pot should be pulled off the fire, set down on the floor as far from the fire as possible, and, if it continue in flames, something should be thrown over it, a sack, a quilt, a coat, a rug, a table-cloth, anything close enough in texture to hinder the access of air to the burning mass, and not itself readily inflammable. The flames will be immediately extinguished. Water would be useless for such a purpose, at least in the quantity readily available. The writer has seen a large pot of flaming turpentine thus instantly extinguished without injury to anyone, and in the very midst of an apartment so full of the most inflammable material that a few minutes' delay would have involved a conflagration.

An overturned lamp should be dealt with in the same way. In this case the lamp will have rolled, and the paraffin will have run, and a flowing river of fire will have to be controlled. One is apt to try to extinguish the whole with the same rug, or shawl, or other cloth, by dragging it from one part to another of the stream. This must not be done, else the part just extinguished is almost sure to be relighted as the cloth is dragged from one place to the other. Shawl after rug, table-cloth after shawl, coat after table-cloth must be thrown on the flames, and one article not moved till the whole is extinguished.

In the case of a curtain set on fire, it must be dragged as swiftly as possible from its hangings, thrown down, and something then thrown over it, as in the other cases. But the person who is engaged with such an accident, especially if the person be a woman, cannot be too careful lest the fire spread from the curtains to her own person. In the case of a curtain the necessity for haste is not so desperate, and a moment or two of deliberate thought, as to how best to proceed to avoid the graver accident, will be well-spent time.

When a woman's clothing has caught fire, the same principles must be applied. She ought immediately to throw herself on the ground, and roll over and over, while she shouts for help. She will often be able, thus, herself to extinguish the flames without help. Even if this happy result be not so easily attained, she delays the flames reaching her face and head, which are, in such cases, the parts often most severely burned, and this delay may be her ultimate salvation. Unfortunately so many persons, in such a desperate situation, so completely lose presence of mind, that the knowledge of what ought to be done is no guarantee of its being done. The first thing, therefore, to be done by any one who rushes to help is to shout to the woman to lie down, and, if need be, to throw her down. The person who rushes to help also runs into danger. This danger is little in the case of a man, but very great in the case of a woman. Either should, on the way, seize rug or shawl, with which, in the act of being thrown down, the person may be enveloped, and by which, when she is down, the flames may be extinguished. This is not so necessary, however, for the man, whose own clothes will less readily take fire; so that, as he runs, he may simply divest himself of his coat,

which he throws over the person in flames, and probably with his hands he will be able to smother out the flames from any part left uncovered.

A woman who goes to help, however, must provide herself with something by means of which she may not only envelop the person, but save her own clothes from catching fire. A blanket, shawl, table-cover, sofa-blanket, would be suitable. This she should hold in front of her, **causing it to trail on the ground**, for if it do not touch the ground, the flames may curl in under its lower edge and set her own clothes on fire before she has been able to render any assistance, and a new victim would be added to the flames.

If the person on fire has already thrown herself on the floor, she should be approached **from the head**, and the blanket allowed to fall on her from the head towards the feet, so that the flames will be extinguished from the head downwards. The rescuer, kneeling down at the sufferer's head, can then, if necessary, push the blanket down over the body towards the feet and press it close to the body and limbs, and so extinguish the flames with little risk to herself.

If the sufferer be rushing distractedly about, it is all the more necessary that the rescuer should be provided with something sufficiently large to interpose a complete barrier between the person on fire and himself, so that the rescuer may, by extending the arms, as in the act of embracing, completely envelop the person on fire, without lifting the lower edge of the enveloping material from the floor. The patient should then be thrown down, and the flames completely extinguished by pressing the covering close in to her body.

It must not be forgotten that it is the limitation of the access of air which extinguishes the flames. Whatever is used, therefore, to throw over the patient must be sufficiently thick and close in texture to achieve this result. Thin, wide-meshed stuff will not be effectual, and may only add fuel to the fire. If, therefore, the material be suited for the purpose, pressing it close to the side of the patient's body, and well down over the feet, is mainly for the purpose of preventing a current of air passing up over the person, and so fanning the flame. The close application of the wrapper to the *parts of the clothing on fire* is not, therefore, necessary, if the wrapper be large enough, and may be actually hurtful, by pressing the burnt clothing, still hot and smouldering, on to the patient's body, and so producing burns of the surface, which might, but for that pressure, have been avoided, and which may have very serious after-effects.

As soon as the flames have been extinguished, the burnt clothing should be removed from contact with the patient, being cut off carefully, and not torn off roughly, for reasons stated fully on p. 999.

THE EFFECTS OF HEAT: BURNS AND SCALDS.

There is no practical difference either in results or in treatment between a burn and a scald; the former is the result of dry heat, the contact with a heated substance, hot metal, &c., the latter is the result of contact with moist heat, hot water, steam, or hot fluid of other kinds.

There are various degrees of injury inflicted by heat, and thus a burn of the first degree is spoken of, or a burn of the second degree or of the third. The difference between these is a difference in the depth to which the injury extends, and this naturally depends on the heat of the substance which has produced the injury and on the length of time during which it was applied.

A burn of the first degree is one in which only the immediate surface of the skin is injured. The part is red, somewhat swollen, and very painful, with a stinging tingling pain, and tender to the touch. That is to say, there is a slight degree of inflammation of the skin and increased flow of blood to the injured part, but there is no blister, and no destruction of tissue, though the surface skin, the epidermis, afterwards peels off.

A burn of the second degree is one in which, owing to the severity of the injury, part of the surface layer of the skin is raised in a short time by the formation of a blister. If the fluid be allowed to escape from it, the raised skin soon dries and protects the irritated surface beneath, on which within six or eight days new epidermis is produced, and the dead dried layer separates, leaving the fresh surface sound and without scar. The pain of this degree of burn is considerably greater than the former. If the dead horny layer of the skin be removed before the new layer has formed a raw surface is left, from which matter may be given off. But soon a scab forms, under the protection of which the new layer is produced. This process may last two or three weeks.

A burn of the third degree extends through the whole depth of the skin and perhaps even into the tissues beneath. The destruction pro-

duced causes sloughing or separation of the destroyed piece of skin, and then a granulating wound (see p. 968) is left, healing with the discharge of matter like other granulating wounds. No new true skin can be produced to fill up the gap, but a scar or cicatrix is left. When such burns are extensive they cause serious deformity by their contraction and consequent pulling upon neighbouring parts. The new tissue formed to fill up the gap has never the full vitality of surrounding parts, and is always evident by its glazed appearance, its greater or less depression below the surface, its tendency to blueness with exposure to cold, and so on. The deformity produced by such extensive burns is sometimes of a very serious character. The contraction of an extensive scar of the neck and side of the head will pull the head down towards one side; that near a joint will sometimes cause permanent bending and diminished mobility of the limb. When the wound has completely healed, rubbing of the part and appropriate manipulation will often effect considerable stretching of the new tissue and diminish the deformity, but the tendency to contraction always remains. It has been thought that the scars of burns have a much greater and more confirmed tendency to contraction than those of other wounds. But it must be remembered that few other kinds of injury produce destruction over such a large and continuous surface, and probably the great degree of contraction is due rather to the large surface over which the scar extends than to any special contractile property.

The length of time which elapses before recovery from a burn of such a degree is naturally very variable. It is always much longer than that taken by slighter degrees, because here there are parts actually destroyed to a greater or less depth. Time is taken by the natural process of repair for the removal of these dead pieces of tissue, and then there is the still longer period required for the filling up of the breach. Moreover, in cases of burns the separation of dead pieces of tissue and the filling up of the gaps produced go on more slowly than in the case of injuries from other causes, which may involve equally extensive destruction. The actual time, of course, depends upon the depth of the destruction and the superficial extent, but the suffering and exhaustion caused by the tedious process are very great.

All these different degrees of burn, it will be observed, depend simply on the depth of tissue involved. In the first case only the immediate surface of the skin is affected, and that to a slight extent; in the second the action of the heat has penetrated partially through the epidermis or horny layer of the skin, in the third it has passed right through the skin and may have reached muscles, tendons, nerves, &c., below. The immediate result and the immediate danger of burns is the shock or state of depressed vital action (p. 990) which they produce. No other kind of injury produces so profound a lowering of the vital functions. This shock is often a very grave condition, threatening speedy death, and, even when it does not end fatally, is much prolonged. On whatever part of the body the burn is situated the shock is great, but it is most marked when it is the chest or abdomen that is affected; and it is more pronounced in women and children than in men. The seriousness of the shock is in proportion to the extent of *surface* involved, not in proportion to the *depth* of the injury. A merely superficial burn of the abdomen or chest of large surface will more readily prove fatal from the depression than a limited burn on an arm or leg, even though it extends almost down to the bone. If a burn involve more than half the surface of the body a fatal result is practically certain. The explanation of this is not clear. Commonly the death is due to the shock to the nervous system. But even when the shock is passed through, death occurs from other causes. In cases examined after death from shock, the internal organs have been found congested, and also the brain, and in cases in which the shock has passed off (in something like forty-eight hours) numerous symptoms point to these organs as being profoundly disturbed. For, following the shock, comes a period of reaction and inflammatory fever, in which, in addition to the bounding pulse and increased temperature, there are dryness and redness of tongue, thirst, loss of appetite, vomiting, and often diarrhœa. These symptoms indicate mischief in the digestive organs, and that inflammation of these organs occurs is shown by blood sometimes occurring in the motions, and by blood and albumin in the urine. Ulceration of the bowel may occur and inflammation of the lungs. The symptoms frequently resemble those of blood poisoning, which has led to one opinion that many of these complications are due to the functions of the skin being interfered with by the large extent of surface involved, and by the consequent retention in the blood of materials which the skin ought to have cast out of the body. Even when the symptoms of inflammatory fever have passed,

which may not be for a couple of weeks, there is still grave cause for apprehension, specially in the case of women, children, old people and persons of indifferent bodily vigour, lest the drain upon the system involved in the prolonged suppuration and the exhaustion of continued suffering may completely undermine the strength and end in death by exhaustion.

The Treatment of Burns and Scalds.—The chief attention in the first place is to be paid to the condition of the patient, and until some steps have been taken in view of the shock which has been sustained the treatment of the injury may be postponed. This immediate treatment has been already sufficiently described under Shock (p. 991). The patient is to be laid flat in bed or on a couch with the head low, great care being exercised in the carriage and moving of him not to inflict further damage on the injured parts. Efforts are to be made to restore animation by the application of warmth to the surface of the body, and stimulants of hot tea or coffee, ammonia in water, whisky in water, or ether, if the shock be profound, are to be administered in one or other of the methods advised on p. 992. While this is being attended to by one person, others may be engaged doing what is needful for the injured parts. As already said, there is to be no hurry permitted in this. In the excitement of the moment persons are apt to proceed to tear off the clothes, thoughtless of the injury they may thereby inflict, and entirely unprepared, when the clothing is removed, with any suitable coverings for the burnt parts. Now two rules must be rigidly adhered to: (1) the clothes must not be *pulled off* the injured parts; they are to be carefully *cut off* by scissors or a sharp knife, and if any portion of clothing is adherent it is to be left rather than forcibly removed, the free parts being cut off; (2) the burnt surface must not be exposed before materials for quickly covering it are ready to hand. So completely ready must the dressings be that the exposure to the air of the burnt surface is of the smallest possible duration, otherwise the shock is likely to be aggravated. Some gauge of the superficial extent of the injury may be obtained from the appearances of the clothing, and suitable dressings may therefore be ready.

It is necessary, at the risk of repetition, to emphasize these points: *attend first to the effort to restore the patient from shock, then arrange suitable dressings, and do not remove the clothing till the dressings are ready for immediate application.*

Now the question arises, What are the suitable dressings? They are such as will protect the burnt parts from the action of the air, and will at the same time soothe them. Dredging the burn thickly with flour or whiting is sometimes resorted to in an emergency, but is not so suitable as the use of oil, because of the crusts it will form with the fluid from the burn, nor is it so likely to be at hand. It is better to cover the part with strips of lint soaked in oil, or sheets of cotton-wool well saturated with oil. In an emergency any oil will do, sweet-oil, almond or olive or salad or castor oil. But the oil most commonly employed is carron-oil, originally made of equal parts of linseed-oil and lime-water, but olive-oil is to be preferred for it. It is a most soothing application, and affords a most grateful relief to the patient. The smell of the preparation is, however, not pleasant, and it does not hinder the parts becoming foul-smelling. Some, therefore, prefer carbolic acid oil, 1 ounce of the carbolic acid to 40 ounces of olive-oil. If the pain be very intense the oil may be made of the strength of 1 of acid to 20 of oil; and this strength sometimes diminishes the sensitiveness of the surface in a very striking way. The carron-oil is, however, perfectly suitable to begin with, and antiseptic preparations may be used later if needful. Sheets of cotton-wool, of abundant size, soaked in this preparation, are then to be got ready and laid, on a plate or tray, by the side of the patient, before the clothing is removed. If blisters have already risen, great care is to be exerted not to tear them open in removing the clothing. If part of the clothing be adherent, cut round it, pour oil upon it, and then cover the whole surface, piece of clothing included, with the oily sheets of wool. If the burnt surface is very extensive, one part is not to remain exposed till other parts have been freed from clothing, but the dressings should be applied bit by bit, just as part after part is uncovered. It will greatly facilitate the process of healing if, in cases of blistering, the raised horny layer of the skin is allowed to remain as a protection to the parts below. All that is needful is to snip the blister at its lowest corner, and at any other part necessary to permit the complete escape of all the fluid, which is to be gently pressed out, and then the dressings applied. The oily covering having been adjusted, a large sheet of cotton-wool, the Gamgee tissue or carbolized gauze or any variety of antiseptic wool (now readily obtainable from druggists), should cover over all, and be fixed by means of a light bandage.

All this time someone must be paying attention to the patient, maintaining the warmth of other parts, administering stimulants, and so on. But the stimulants must be given with great discrimination in view of the subsequent inflammatory fever. The stage of shock will last from two or three hours up to twenty-four or forty-eight, according to the extent of the burn and the sensitiveness of the patient. The person must be guided by the pulse, the breathing, and the appearance of the skin, and on seeing indications of revival refrain from further use of stimulants, at the same time watching against a relapse.

The time of re-dressing must be determined not only by the state of the injury but also by the state of the patient. It is certain to be painful, perhaps exquisitely so, and to subject a patient to such pain who had hardly recovered from the shock of the injury would be very improper. It is indeed often deemed proper by surgeons to carry out the first one or two re-dressings with the patient under chloroform. The first dressing may quite safely be left for two or three days if the discharge from the burn is little or none, and there is no foul smell. But the appearance of any foul smell should suffice to determine its being immediately done. It must be carried out with equal care to the first. The new dressings are all to be ready before the first are removed; the first are never to be torn off. If adherent, they must be soaked by streams of water containing an antiseptic such as carbolic or boracic or salicylic acid, and the old dressing should be removed bit by bit, the new being applied in the same way. Any pieces of clothing left on the first dressing may now be easily removed by the stream of water. Where the destruction passes deeply into the tissues, so that sloughing is caused, frequent re-dressing and cleansing with antiseptic solutions becomes a necessity to prevent the putrefying appearance and odour of the separating pieces. Besides the carbolic lotion, Condy's fluid may be used for this purpose, or the perchloride of mercury lotion. Indeed, when the burn has reached the stage when the destroyed portions are separating, and still more when these dead pieces are separated and the wound is granulating, must the treatment adopted be similar to that already described for lacerated wounds, or a wound healing by granulation (refer to p. 968). When the scar tissue is forming and beginning to contract, great care and much patience and ingenuity require to be exercised to diminish deformity. In severe burns it is impossible to prevent all deformity, but it may be much lessened by the application of splints to hinder forced bending of joints, and by kneading, rubbing, and other manipulations when the wound has closed over.

In order to shorten the process of healing over of such extensive wounds, and to diminish deformity, the process of **skin grafting** has been introduced. This consists in snipping off from some healthy part of the body small pieces of skin, not throughout the whole depth but only from the surface layers of the skin. These fragments are planted on the surface of a healthily healing part of the surface of the wound, and hasten its covering in, lessening also the amount of shrinkage of the scar. A much more satisfactory method, however, consists in the transplanting of considerable pieces of skin. The size of the piece desired is marked out on a piece of paper, and this is laid on some part of the healthy body, arm or leg, and the extent of surface needed to be transferred thus accurately determined. This mapped-out piece of skin is now carefully dissected off with a clean sharp knife, the whole thickness of skin being removed. When the piece has been cut out, it is carefully trimmed, all fatty tissue from the under surface of the skin flap is carefully removed by scissors, and it is then placed in position on the desired portion of the wound, which has been cleaned and dried previously. The author has seen a piece of skin of the size of a half-crown piece thus removed from the arm and transplanted to the upper eyelid to fill up a gap, left after the cutting out of a piece of scar tissue by whose contraction the eyelid was being turned inside out, everted. The transplanted flap was retained in position simply by the pressure of clean lint and a lightly applied bandage. It took root, so to speak, became completely incorporated with the surrounding parts, and indeed almost indistinguishable from the surrounding skin, the form of the eyelid being very satisfactorily restored. When, first, flaps of skin were transplanted it was thought to be necessary to retain a connection by a sort of bridge of tissue with their old site, by which some blood supply was maintained till they had formed a connection with the new locality. This implied the removal of the transplanted flap from the immediate vicinity of the wound, or if the flap were removed from the arm to some part of the face it meant the binding up of the arm into close proximity to the face, and in a painfully constrained fashion, for many days. The newer method, which has shown that the skin may be completely sepa-

rated from one place and yet retain vitality enough to become an integral part of another part, is due to Dr. Wolfe, of Glasgow, who has on several occasions employed it for the restoration of eyelids. It is especially serviceable in the case of scars of the face from burns or other injuries, which may seriously spoil the person's appearance, and in the case specially of a woman be a cause of much annoyance. In these instances the scar of the old injury is simply dissected out, a piece of skin the requisite size is removed from some part of the body, usually concealed by the clothing, and transplanted to the face. The new wound, thus produced, is allowed to heal up in the usual simple way. Professor Esmarch of Kiel has published (1889) the details of several operations he has performed by Wolfe's method on the face with great gain to the personal appearance of the persons.

Now we have described in detail the treatment of extensive and deep burns, which end in scarring. The treatment of burns, in which no great thickness of skin is affected, in which there may be blistering but no scar, is comparatively simple, except for the shock, which, as already said, may be even more grave than that attending deep burns of less area. The oily applications need less frequent renewal than in cases where there are sloughing and discharge, and from first to last nothing but oily applications may be necessary. The carron-oil may be used to the end without fœtor or discharge if the skin of the blisters have not been removed. To prevent smelling without giving up the use of the carron-oil some carbolic acid may be added to it (1 ounce of the acid to 40 of the carron-oil).

Many other applications are advised, specially at first when the pain is great. Among others, a saturated solution of common washing soda is advised as affording great relief, and a thin ointment of iodoform and vaseline. A mixture of chalk or whiting and vinegar is also praised for the speed with which it relieves pain.

For slight and merely surface burns immersion in cold water for a few seconds at a time will be found very soothing. Cold water applications laid on and left for any time are useless; they become so speedily warm. But if a stream of cold water be allowed to flow over the part for half to one minute at short intervals, or an iced cloth be applied, great relief follows for a little. When the stinging pain has thus been removed, enveloping the part in a thin layer of antiseptic wool or gauze is afterwards sufficient. Of course if the burn covered a large surface, however superficial it might be, one would be slow to use cold water in this way unless all fear of prostration had passed away.

These, then, are the means of treatment usually recommended to be employed. The author, however, has experience of another method, and though it is many years since it was applied on his own person he has still grateful recollections of its ease and its pain-relieving character. It consists in treating the burn by the application of carron-oil, but without any dressings whatever. The carron-oil is applied by means of a feather or brush on the burnt surface, into contact with which neither lint nor cotton nor any material whatever is allowed to come. It is only applicable to burns of the first and second degree, and not when there is separation of parts. The person lies in bed with the part quite uncovered and yet under the bed-clothes, this being accomplished by some contrivance which keeps the clothes off the skin. This is easily arranged. A wire guard can be procured to be placed over the burnt member, arm or leg, or to span the chest or abdomen or neck; and it bears the weight of the clothes. The person is kept perfectly warm, although the bed-clothes need not touch him at all except about the head. Such a guard can be easily improvised by using an ordinary wooden box or drawer. When the drawer is wanted to cover a leg or arm, one end is knocked out, and the box then placed over the limb. In the case of the leg it should be deep enough to permit the foot to rest on the heel. In the case of chest or abdomen, both ends are knocked out, and the box then placed over the body. With such an arrangement it

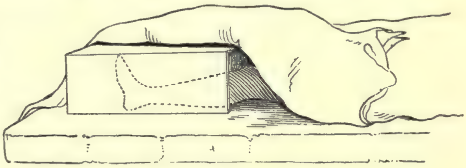

Fig. 374.—Protector for Burnt Leg.

is exceedingly easy to turn the bed-clothes partially down in order to reapply the carron-oil at frequent intervals. The surface is thus kept cool and comfortable and the pain and distress of each re-dressing completely avoided. Fig. 374 shows a common kitchen drawer prepared and in use for such a purpose.

Burns from Explosions of Gas, gunpowder, from contact with burning clothes, and so on, are to be treated on precisely the same lines. Every now and again one reads of severe injuries sustained by a person's clothing catching

fire, and the person being extensively burned on face, hands, arms, neck, &c. Many of these accidents issue fatally, not from the actual injury, but from the combined shock of terror and the large extent of surface involved. Very many such accidents might be reduced to small proportions, if the person did not lose all presence of mind and go rushing about from place to place, and if spectators did not also lose presence of mind in witnessing it. A person whose clothing catches fire may quickly smother out the flames in many instances, at the risk of burning the hands, by firmly grasping the clothing and covering over the flaming parts with other portions unattacked. Or the person may throw herself or himself on the floor, and by rolling over on the part in flames extinguish it. Or the person may envelop herself in a plaid, overcoat, rug, shawl, &c., and then roll on the floor. Anyone near may help to extinguish the flame by throwing the person down and smothering out the flame with his hands or his own garments, or throwing a rug over the person, tightly enveloping him or her.

Scalds of the Mouth, Throat, and Gullet.—These accidents are more common in children than in adults, and are in children often due to the trick of drinking from a teapot or kettle spout. When the scald is limited to the fore part of the mouth the danger is not great, but great pain is caused, and the tongue may swell so much as to be forced out of the mouth. Cold water immediately used and freely and frequently repeated is advised, and, later, to the cold water a few drops of carbolic acid may be added, the mixture being well stirred before use. Sips of cold milk and iced milk are to be frequently given, and small pieces of ice to suck. When the throat and top of the gullet have been reached, the case is much more serious, for the top of the box of the windpipe is necessarily affected, and the swelling which very speedily arises may threaten to cause death by suffocation. A surgeon must be immediately sent for, since in the event of such a result being threatened, it may arise in a comparatively short time, and opening of the windpipe is the only sure means of permitting breathing to go on till the swelling subsides, though scarification may reduce the swelling sufficiently to prevent suffocation. In the meantime sips of iced water and iced milk are to be given, and small pieces of ice to suck. Of course shock will require to be treated as already described on p. 991. Even when the risk of suffocation has been averted, serious danger is not all past. If there has been any destruction of tissue in the gullet a scar results, and as healing goes on the resulting contraction may so diminish the diameter of the tube as to produce stricture, and render swallowing difficult if not ultimately impossible.

Burns from Chemicals, strong acids, such as vitriol, nitric acid or aqua fortis, spirit of salt, strong carbolic acid, quicklime, caustic soda or potash, are produced with great rapidity. The action of any of these substances penetrates deeply and quickly, producing destruction to a considerable depth, and always causing sloughing and scarring. So quickly are they produced that there is almost no time to obtain anything fully to antagonize their effects. Such acids will quickly burn through clothing. Cold water will probably be at hand in most instances, and is to be used freely. If the substance has passed over any extent of surface no mere washing will do. If abundance of water is at hand, the person should not hesitate to plunge into it and freely move about in it; or the limb affected should be thrust in and moved rapidly to and fro, or the head should be dipped in. No time is to be wasted removing clothing, the instant dilution of the substance with water is desired. In the case of acids any alkaline substance at hand, soda, lime, &c., should be added to the water to neutralize it; and in the case of lime, caustic potash or soda, acid—vinegar, for example—should be added. After this has been done, and as much of the corrosive substance removed as possible, the part may be treated as for an ordinary burn or wound.

Such corrosive substances are sometimes swallowed by mistake. Large draughts of water should be taken; in the case of acids, lime and water, soda and water; and in the case of solutions of caustic soda or lime or potash, vinegar and water. In the case of vitriol it must be remembered that the addition of water to it develops great heat, and great quantities of water would require to be taken rapidly. Lime could be torn from a wall and given with water. The immediate attendance of a medical man is necessary, for should the shock and other immediate effects be recovered from, prolonged and exhausting illness from ulceration and sloughing of parts is certain to follow, if any has reached the gullet and stomach. Indeed such cases are usually speedily fatal.

Burns of the Eyeball and Lids with dry heat, hot metal, &c., are to be treated with the atropinized castor-oil mentioned on p. 369. If lime has reached the eye a wash of vinegar and water, *never water alone,* is to be used, and if acid,

a solution of soda or lime-water, or water alone, except in the case of oil of vitriol.

Sunstroke (*Heat-stroke, Heat-fever, Coup de Soleil, Insolatio*). Sunstroke appears really to include several diseases. There is first of all the form due to exposure to the direct rays of a hot sun, especially when they have been beating upon the head and neck. The liability to the attack is increased if the air is much heated, and if the person has been engaged in any laborious or exhausting occupation. Thus soldiers on the march, carrying heavy accoutrements and cumbered with clothing, are apt to be smitten in large numbers. This is common, wherever the direct heat of the sun is very great, and not only in India and tropical countries. It is also known in England. The symptoms very often arise suddenly, the person falling down insensible, and exhibiting all the symptoms of extreme nerve shock. The pulse is feeble and rapid, the breathing gasping, the skin is pale and cold, and death may occur quickly from failure of the heart and the breathing. These effects seem to be due to congestion of the brain and other nerve-centres; and if recovery occurs, while it may be complete, it is often imperfect, permanent changes in nervous structures leading to impaired intellect and generally enfeebled health.

Sometimes there are symptoms previous to the attack warning of its threatened onset. These are a feeling of great weariness and prostration, dizziness, sickness, restlessness and sleeplessness, dryness and heat of the skin, and incontinence of urine or a tendency to frequent passing of water.

But another form of the disease may occur, altogether without exposure to the direct rays of the sun. This may be produced by working in air heated by the sun's rays or by artificial means. Persons working in a confined space, with impure atmosphere, especially if depressed and exhausted by work, fatigue, or dissipation, or in a poor condition of general health, may be attacked. It is frequent in the case of soldiers in hot confined barracks, workmen, stokers or engineers on board ship, specially in hot climates. In summer such cases occur in many of the large swift steamers, where the men are kept working in the very hot and close atmosphere of the engine-room or stoke-room. This is specially apt to happen in certain conditions of the atmosphere, when the air is still and laden with moisture. In countries, such as Bengal, where the atmosphere is not only warm but damp, the liability to such an attack is greater. For a hot atmosphere which is also dry is tolerated far more readily than one which is moist. In the dry hot atmosphere, evaporation from the skin is encouraged, and the temperature of the body kept down, but this is prevented in the case of air already laden with moisture. This variety is called **heat-fever**, or **ardent fever**, and is common in India, attacking not only foreigners but natives also, though the latter can tolerate a much higher degree of heat than the former. To this variety also persons with enfeebled general health more readily succumb than those of sound and vigorous constitution, who live healthy temperate lives free from any vitiating influences. The attack may occur in the shade, at night, just as much as in the daytime or in the sunlight, provided the person is under the depressing influence of a close confined atmosphere, vitiated by overcrowding.

In cases of this variety the fever induced by the heat is very high. There is great weakening of the heart, the breathing is quick and gasping, the skin burning, thirst is great, and there is marked restlessness, and frequent calls to pass water. The skin of the face, head, and neck is congested with blood and livid; and the pupils dilate widely before death. If death is about to occur, its approach is heralded by delirium and convulsions, stupor, involuntary evacuation of the bowels, and suppression of urine. Recovery may occur, but not complete, impairment of intellect and feeble health being the consequences of inflammatory changes in the brain and injury to other organs. Recovery may seem to set in to be followed by relapse. When death occurs it is usually within twenty-four or forty-eight hours.

Symptoms may occur for some hours or even days before the illness develops, significant of what is about to follow. A general feeling of ill-health, restlessness, and sleeplessness, disturbances of bowels and bladder, sometimes thirst, loss of appetite, a feeling of sickness, giddiness, headache, a feeling of anxiety, and a sense of impending evil, and quick short breathing are among these premonitory symptoms.

A milder form of illness due to exposure to a hot atmosphere in the circumstances already mentioned is called **heat exhaustion.** Its symptoms are those of nervous collapse, the skin is cold, pale, and clammy, pulse quick and weak, there is complete prostration of muscular strength, and while complete recovery may be effected by appropriate treatment, death may take place suddenly from failure of the heart.

Treatment of Sunstroke and Heat-fever. In the last condition mentioned, that of heat exhaustion, the patient should be removed to a cool room or place where the atmosphere is fresh. All heavy and tight clothing should be removed or loosened, cold should be applied to the head and back of the neck either in the form of an ice cap or in the form of a cold douche. The application of cold, however, must not be pushed too far, lest it lead to further depression of vital powers. For the rest, stimulating treatment may be needful; smelling salts, not too strong, should be held to the nostrils for an instant or two at intervals; weak liquor ammonia, 15 drops at a time, well diluted with water, may be given by the mouth, or weak spirit and water, and nourishing food must also at frequent intervals be administered if possible. At the same time stimulants must be administered with great caution, and discontinued as soon as signs of returning animation appear. If rashly and inconsiderately used they are certain to aggravate the condition of reaction which follows the collapse. It may be necessary to maintain the breathing by artificial respiration.

In the case of heat-fever, cold is also to be applied to the head and spine, as an ice bag or cold douche. Here again care must be taken not to produce depression. But the ice application may be continued at frequent intervals until the heat of skin abates and the fever is reduced. This should be ascertained, if possible, by a thermometer whose bulb is passed up into the bowel (see p. 10). If consciousness does not return, blisters may be applied to the nape of the neck, and, after shaving, to the back of the head. The bowels should be freely relieved, though not powerfully purged. The use of food and stimulants may be adopted on the lines already indicated. At one time bleeding was advocated to relieve the turgid and livid appearance of the head and face and the laboured breathing, but is not now advocated, it being recognized that any measures which further reduce the patient's strength are only likely to make a fatal termination certain.

When a person drops suddenly to the ground with sunstroke, he is to be immediately removed to the shade and a stream of cold water is to be poured from a height upon his head, neck, and body, as he lies stretched out on the ground. All tight and heavy clothing should be removed; and if the cold water be immediately and freely applied a return to consciousness will very often be brought about. Injections to relieve the bowels, and mustard applications over nape of neck and heart, may be required.

Any person who has suffered from any form of sunstroke should be exceedingly careful to avoid any subsequent exposure. Those who have recovered either wholly or partially from the severer forms should seek immediate removal to a cooler climate. Even in a temperate climate much exposure to a warm sun should be avoided; regularity in habits of body should be rigidly practised; and the person should abstain completely from all forms of alcoholic stimulants.

The mortality from sunstroke is estimated at between 40 and 50 per cent, and of those who do recover, many retain some permanent indication of the attack in some form of nervous weakness or disturbance of greater or less severity.

Lightning Stroke.—Death may be caused instantaneously by lightning and no trace of its action be visible, the sudden shock to the nervous system having immediately arrested the vital functions. In other cases evidence of the stroke is found in greater or less amount. Wounds may be produced of a character to mark off one in the position where the current entered and another as its point of exit. The clothing may be rent and torn from the body with great violence; boots may be riven in pieces, metallic bodies in the pockets, a knife, keys, a watch or chain, may have attracted the current and be fused, broken to pieces, or magnetized. The body itself may suffer in a great variety of ways, internal organs may be disorganized, and the skin may be scorched. Scorchings of the skin very often assume a curious branching tree-like arrangement according to the way in which the electric fluid has swept over it. It was at one time a popular belief that such markings were photographs of some tree in the neighbourhood of the place where the person was struck. A person may be so struck that a limb is separated from the body, though this is not common. A person who is not directly struck, but is in the immediate neighbourhood of the place struck, may yet be seriously injured. The effects resemble those of concussion of the brain (see p. 104), weak pulse, slow feeble breathing, dilated pupils; and the person may remain unconscious for a considerable time, from a few minutes to hours or even days. The effects produced may be but slight, sudden giddiness confusion, faintness, recovered from in a few minutes. The more serious cases may be attended by paralysis of the limbs or affection of

the senses, blindness, wholly or partially, loss or perversion of smell, deafness or noises in the ears, &c., loss of memory and some affection of brain may remain. Paralysis arising from lightning stroke may be removed sooner or later. Trees are very often struck by lightning, and it is regarded as unwise to take shelter under them during a storm, but the beech-tree is said never to be assailed, and it is in many places believed that it is impossible for one sheltered under it to be struck.

The treatment of lightning stroke consists at first in the treatment appropriate to concussion of the brain or nervous shock from other causes. Efforts are to be made to restore animation by friction of the limbs, the application of warmth to the body, and, if it appear needful, the judicious use of stimulants. The cold douche suddenly applied and quickly suspended is said to be of great value for rousing the circulation and breathing. Breathing may require to be maintained artificially.

Electric Shock differs in no essential particulars from lightning stroke, when it is received in sufficiently intense currents to be injurious. Any differences that occur are only differences in degree. Death by electricity is unhappily becoming now a common accident, in many cases being attended by features of special horror. Reports of electric lighting employees being killed by electric shock from overhead wires while working on house roofs, and of the body, entangled by the wires, being slowly scorched, are becoming painfully numerous. Persons cannot be sufficiently on their guard against touching in any way any electric conductors, and specially against touching or stepping on any overhead wire that may have fallen and be lying on the footway. Though it might be only a telegraph or telephone wire it is wisest to err on the safe side.

THE EFFECTS OF COLD.

Long-continued cold acting upon the whole body produces general depression, which is manifested by a feeling of coldness and chilliness, followed by uneasy tingling of the body. The skin is pale and corrugated. The body gradually feels benumbed, and with the languid circulation a sense of languor and drowsiness creeps on, to which the person is almost irresistibly inclined to yield himself. His muscular power becomes very feeble; he is oppressed with a feeling of weight and an intense desire to sleep; his ideas are confused and his mental faculties blunted, and if not almost forcibly prevented he yields to the languor that overpowers him and lies down. The cold continuing to act upon him, the heart's action becomes feeble, quick, and irregular; breathing is laboured and slow; the pupils of the eye dilate; a heavy stupor overtakes him, ending in death. In other and less extreme cases the effects upon the nervous system are manifested, not in stupor, but in delirium, wandering or raving in character, and sleeplessness.

The **treatment** of a person thus overpowered must be carried out with great care. It is universally admitted that any sudden change from the state of cold to one of heat is to be entirely avoided as likely to prove fatal. The restoration of warmth must be very gradual. The person should be divested of his clothing and laid, rolled in cold blankets, in a *quite cold room.* Rubbing the body with ice or snow is commonly recommended, and this may be alternated with light friction with cold flannel or fur. This must be persevered in for hours if necessary. When the patient shows signs of returning animation the room may be very slightly warmed. With the return of consciousness pains may be complained of in the limbs, especially if they have been warmed too rapidly, and it is deemed advisable to envelop the limb in cloths soaked with cold water. As gradual relaxation of the stiffened parts occurs, some slightly stimulating liniment may be employed with which to continue the rubbing—soap-liniment, tincture of arnica, or camphorated spirit. Mildly stimulating drinks are then given, warm tea, coffee, beef-tea, or soup, but no alcoholic stimulants till later. In fact the restoration of the bodily heat must be brought about very gradually throughout, and the frictions of the whole body must be steadily maintained but never in too vigorous a fashion. *The efforts at restoration must be persisted in for many hours.* The following case, occurring in America, may be given in illustration: "An Esquimau had his leg frozen above the knee-joint, stiff, colourless, and to all appearances lifeless. He was placed in a snow-house, at a temperature of 20° *below* zero (Fahrenheit). The parts were bathed in ice-cold water for about two hours, and then enveloped in furs for three or four hours. Then frictions were used, first with the feathery side of a bird-skin, then with snow, alternately wrapping the limb in furs and rubbing it for nearly twenty-four hours. It was next carefully wrapped up, and the temperature of the snow-house raised by lamps above zero. On the third day the patient was taken to his

house (in the Esquimaux houses there is often a temperature of 70° or 80° Fahrenheit), and in seventy hours was walking about, with only a slight frost-bite on one of his toes." "This case," adds the narrator, Dr. Hayes, "shows how much may be accomplished with care and perseverance, even under the most adverse circumstances."

Some interesting experiments made by Pflueger, a German physiologist, throw some light on the cause of the difference between slow and rapid warming after an intense degree of cold. He experimented with frogs, and after freezing a frog till it was as hard and stiff as a board, he thawed it out very slowly, with the result of restoration of animation, the frog being able to jump about though in a languid way. The author has himself seen a frog hopping about, which, hours before, had been frozen hard in a Bell-Coleman freezing-machine. The idea of Pflueger's explanation is, that if rapid thawing occurs the waters of the tissues separate out, and the tissues are left in a moist dead state, while if the thawing be accomplished slowly enough the water is taken up and organically incorporated with the reviving tissues.

A person who is subject to intense and long-continued cold must be encouraged to move actively about. The desire to sit down and yield to the languor must be combated in a most determined manner. Stimulants, at least alcoholic stimulants, are not to be administered. They are harmful rather than useful, because, as explained on p. 673, they rather accelerate the loss of heat from the body by dilating the blood-vessels of the skin. A sharp, clear, dry cold is much less hurtful than a damp cold, for the moisture of the latter soaks the clothing and causes them to become better conductors of heat, so that heat is lost from the body with much greater rapidity. Naturally, persons who have been subject to prolonged fatigue and insufficient nourishment will yield to the influences of cold much more rapidly than those who are fresh and well nourished. While alcoholic stimulants are objected to, warm stimulating articles of food, that is to say substances which nourish as well as stimulate, warm soup, beef-tea, milk, &c., may be freely taken by those exposed to cold.

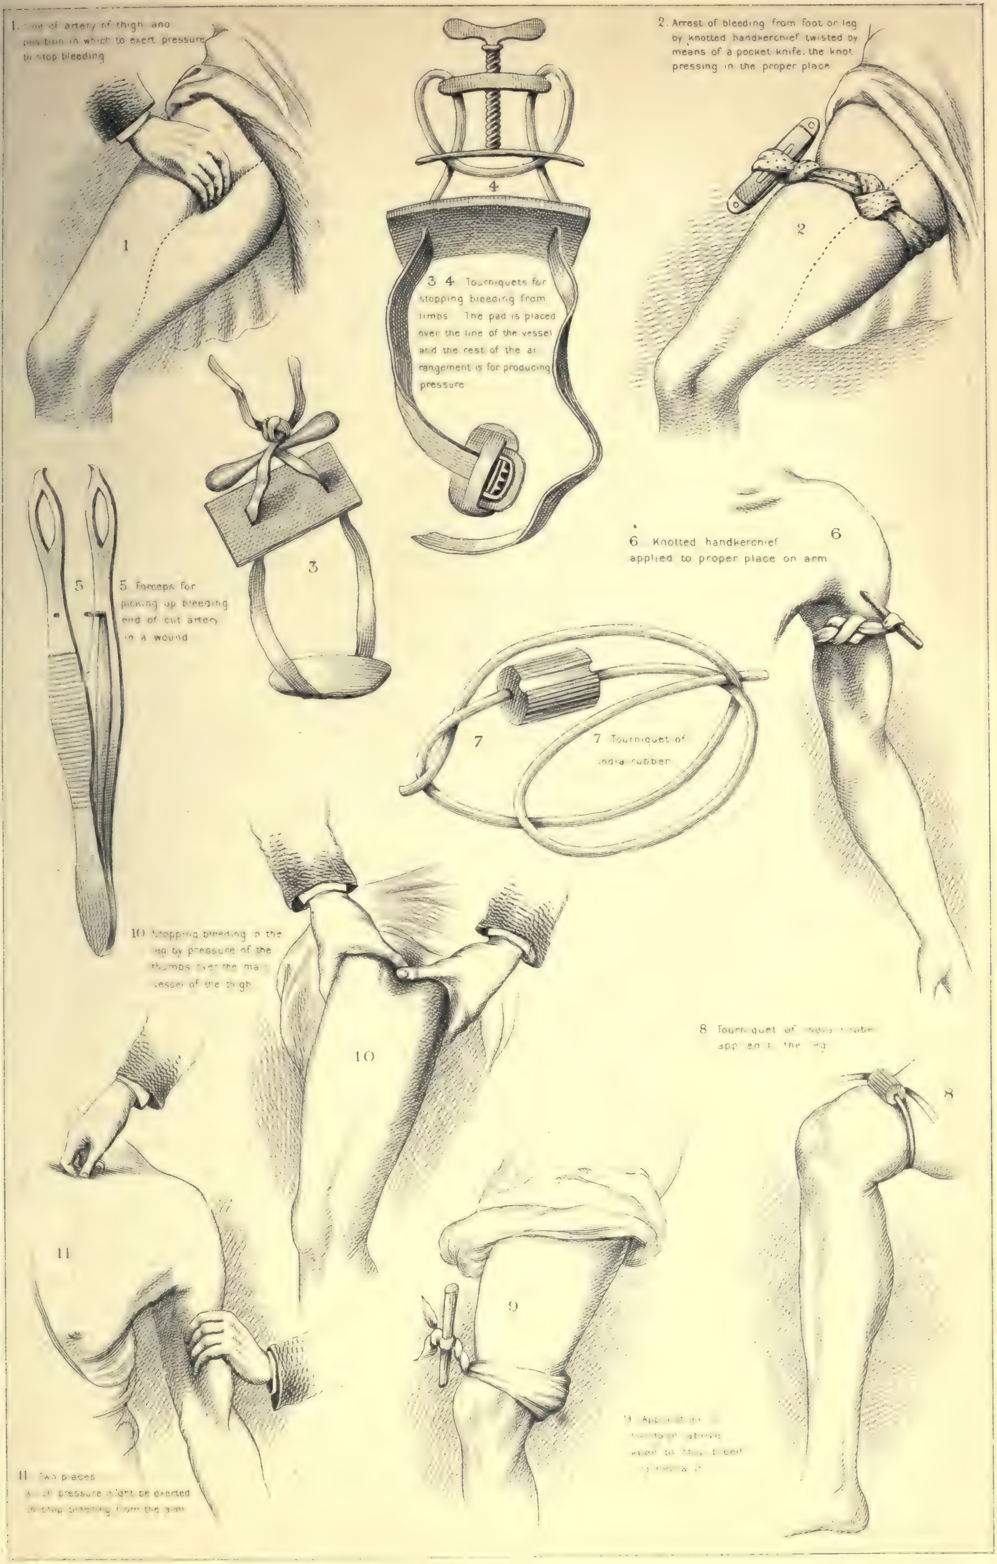
As a protection against external cold nothing is equal to a fair quantity of fat in and underneath the skin. The thin man will, other things being equal, succumb long before the fat man. Then in cold weather and cold climates the heat-producing articles of food, specially fat, should be freely consumed (see p. 619), and non-conductors of heat used for clothing (see p. 723).

Frost-bite is the condition of coldness, numbness, and loss of power attacking a part of the body, exactly the condition already described as affecting the whole body, but limited to a part of it. The parts usually affected are the extremities, the toes and fingers, feet and hands, nose and ears, because these are the parts at greatest distance from the centre of circulation. There are various degrees of frost-bite, as there are various degrees of burn. The frost-bite may only be sufficient to produce coldness and numbness of the affected parts, the skin of which becomes white and wrinkled; and, when heat is restored, marked reaction occurs with redness, heat, tingling, itching, and swelling of the parts. The more rapidly the change from cold to heat occurs, the more marked and violent is this inflammatory reaction, but it soon subsides, and restoration to the normal state occurs. If the cold be more intense and longer applied a second degree of frost-bite occurs. Complete loss of sensation takes place; the parts become discoloured, blisters form filled with fluid, which may be clear but is often bloody. If the cold have been so intense as to freeze the part through and through, it will be hard, stiff, and brittle, and in this state the part might actually be separated from the body by breaking. Usually, however, the parts are purple, have lost feeling, and, if pricked, only a drop of dark blood escapes. One must not conclude that restoration of such parts is hopeless; for by appropriate and careful treatment recovery from even this degree of frost-bite is possible. In a greater degree of frost-bite the death of the part is complete, it passes into a contracted shrivelled condition, and drops off from the body, a red line of demarcation marking the separation between the dead and the living. That is to say, the part separates by gangrene.

The **treatment of frost-bite** is identical for that already described for the whole body benumbed by cold. Under no circumstances must a sudden change from the intense cold to heat be indulged in. A person who, after long exposure to cold, at last reaches shelter with a hand or a foot or fingers or toes in this benumbed condition, is apt to seek the immediate aid of external heat, of a warm fire, of hot water, and so on. This is attended by grave danger not only to the benumbed parts but also to the whole body. Numerous illustrations of the danger of such procedure are derived from the

METHODS OF ARRESTING BLEEDING.

Plate XVI.



experience of armies in the field. Soldiers, exposed for long periods to the cold, at last seek the warmth of the camp fire and stretch out their benumbed hands and feet to the blaze, only to determine gangrene of the extremities by the sudden transition. It has even been noticed that such results followed, in the case of troops exposed to a cold night-watch, if a sudden thaw set in, the mere natural transition from a low to a much higher temperature being badly borne by the frost-bitten parts.

The treatment, then, that is invariably advised is gentle friction, at first with snow or ice-cold water in a cold room, and a very gradual elevation of temperature as a gradual return of animation becomes evident. As the limb begins to approach the normal degree of heat, it may be wrapped in flannels or furs or cotton-wool. If the part does not recover, the separation about to be effected by gangrene is revealed by the appearance of a red zone between the living and the dead parts. In the case of fingers and toes, warm linseed-meal poultices are commonly employed to aid the separation of the slough. To keep down smell antiseptic dressings are employed as in the case of wounds, and when the dead part has been removed the stump is to be treated in the ordinary way as a granulating wound (p. 972). During this period the strength of the patient requires maintenance by nourishing food, perhaps also by stimulants and tonics. In the case of a foot or hand or a large portion of a limb, as soon as gangrene became evident, a surgeon would perform an amputation to save the patient the prolonged suffering and exhaustion of the natural method of separation, and to get rid of the risks of blood poisoning which might otherwise arise.

Parts which have once been frost-bitten and have recovered are liable, on a repetition of the exposure, to a repetition of the attack. Care should therefore be taken, by the use of extra protection by woollen material or fur, to guard against such a return.

The milder degrees of frost-bite require caution in the application of heat, but are usually rapidly recovered from. Rubbing with snow, and subsequent wrapping of the parts in flannel or fur with gradual elevation of temperature, will commonly suffice; and, when the parts are restored to a normal degree of heat, light friction with some of the stimulating liniments or ointments recommended for chilblains will be useful.

Chilblains are degrees of the effects of cold milder than frost-bite. A part of the skin is in a state of inflammation due to cold. There is some amount of swelling, redness, heat and tingling, and the itching pain is increased by heat. The patch of skin, in cases of greater severity, may be purple or livid, and blebs or blisters may form upon it. The blisters may break and leave a suppurating or ulcerating surface.

The treatment of chilblains is conducted on similar lines to that of frost-bite. Warmth is not to be restored, after the exposure, by hot water or by holding the part before the fire. Rubbing with snow or iced water is again recommended, or simple gentle friction with the hands. Later a liniment of opium or soap and opium, and subsequently a more stimulating liniment, such as camphor liniment or turpentine liniment or tincture of iodine, are recommended. If the skin is not broken ointment of iodine is said to be one of the very best of applications. After this the part should be enveloped in flannel or carded cotton.

While the fingers and toes are usually attacked, the nose and ears frequently suffer; and if in one winter season the ears of a person have become affected, the probability of a recurrence the following season should be remembered and precautions taken.

Young persons are specially prone to be attacked by chilblains, and specially such as are not of vigorous constitution.

The prevention of chilblains is better than their cure; and if it is remembered that it is not the mere exposure to cold that determines their occurrence, but the sudden change from severe cold to heat, one of the chief means of prevention is indicated. Persons with chilled fingers or toes *must keep from the fire* till the heat of the parts has returned naturally. Then, of course, efficient protection should be provided for hands, feet, ears, &c., by the use of suitable clothing, woollen stockings, snow-shoes, woollen gloves, &c. Active exercise during exposure to the cold, and rubbing, should be engaged in to prevent the numbing of parts.

SECTION V.—SUFFOCATION OR ASPHYXIA. RESTORATION FROM THREATENED DROWNING, CHOKING, HANGING, STRANGULATION.

Suffocation or Asphyxia:
Its Causes, Stages, and Treatment;
Suffocation from Foul Gases and its Treatment.
Drowning:
Methods of Artificial Respiration—Sylvester's, Howard's, Marshall Hall's.

Hanging and Strangulation.

SUFFOCATION.

Suffocation is the condition which arises when an animal is deprived, by any means, of a due supply of air fitted for maintaining the proper condition of the blood. In Part I., Section IX., p. 249, the purpose of breathing has been described at length. Its purpose is two-fold. The gas called oxygen is needed in the body to effect the chemical changes by which the nourishment taken is converted into power of doing work or energy, and into heat, and by which the integrity of the body is maintained. By the work of the body a gas, called carbonic acid gas, is produced, which if allowed to remain in the body becomes speedily injurious, acting as a poison. The fuller explanation of these facts will be obtained in the section already named, and in the early paragraphs on food, p. 531. Now the lungs are the organs by which at once new supplies of oxygen are introduced to the blood and carbonic acid gas removed from it. We do not breathe pure oxygen, but the ordinary atmospheric air we breathe contains oxygen, diluted with a neutral gas, nitrogen. Now any circumstance which will prevent the blood obtaining its proper supplies of oxygen will produce symptoms, more or less marked according to the degree to which the oxygen is wanting. These are symptoms of suffocation, using the word in its scientific sense, or, to use the scientific term, **asphyxia** (Greek *a*, not, and *sphuxis*, the pulse). The literal meaning of this word is, therefore, pulselessness, though it is used to mean the condition described. The early symptoms, and the symptoms which arise when the deficiency of oxygen is not great, would not be popularly recognized as symptoms of suffocation, but simply as symptoms of difficult and laboured breathing (p. 284), or **dyspnœa** (Greek *dus*, with difficulty, and *pneo*, I breathe), for in the popular mind the term suffocation is used to imply the condition in which the person is, from want of breath, in immediate danger of death. Nevertheless, these symptoms are merely the early symptoms of a slight degree of that condition in which oxygen is not gaining entrance to the blood, which, if it becomes aggravated, is readily recognized as a state of suffocation.

It is quite clear, then, that suffocation or asphyxia may arise from a great many causes, and not merely from the commonly recognized cause of blocking the windpipe by pressure from without or by something falling into it from the mouth. Suppose a person's lungs are in thoroughly good order, but he is placed in a small confined space into which no fresh air can enter. By and by he will so have exhausted the supply of oxygen in the air of that apartment that he can get no fresh supplies into his blood. He will die from want of fresh air, from want of oxygen, from suffocation, just as much as if he had been seized by the throat and strangled. Of course there will be an additional element present, namely, that he has not only removed from the air all the oxygen he can, but he has polluted it with carbonic acid gas and other exhalations from his lungs, so that it will not be a pure case of suffocation, though it is that chiefly. Again, let us suppose that there is abundance of fresh air about a person, but that both lungs are blocked up with products of inflammation, as in inflammation of the lung, and that the air cannot penetrate to the recesses of the lung to reach the blood. Again he will die of suffocation, not from want of air or of oxygen in it, but because he cannot make use of it, the inflammation being the cause of his inability. Or let us suppose he has pleurisy of both sides, and that large quantities of fluid have been poured out round the lungs, causing them to be squeezed up into a corner of the chest, emptied of air, and prevented expanding, asphyxia again arises. Still again let us suppose that the atmosphere about him is pure

enough, and that his lungs are in a healthy state, but that there is a growth in his windpipe which gradually encroaches on its fairway till the passage for air is seriously blocked, clearly suffocation will arise. Take the case of membranous croup, diphtheria of the larynx or box of the windpipe in a child. The membrane which grows in the larynx rapidly narrows the passage for the air, and the child gasps and fights for the air that is around it in abundance, but which cannot pass the narrowed part of the tube sufficiently quickly for its purpose, and finally, if the membrane continues, the child dies of suffocation, worn out too by its struggles for breath. Once more, suppose a mass of food has "slipped down the wrong way" and gained entrance to the windpipe, which it blocks, suffocation again immediately arises, the person is deprived, at a stroke, of oxygen by the block in the pipe. Lastly, suppose the mouth and nostrils are stopped, or the windpipe closed by the hand of a garroter, or by the person's head being buried in sand or earth, or immersed in water, as in drowning, or the windpipe compressed, as in hanging or strangling by a rope, clearly the result in all cases is the same, no new supplies of oxygen gain entrance to the blood, and in all the death is by suffocation or asphyxia. If a person or animal were to be lowered into a pit or jar containing nitrogen gas only, the same condition would arise, death from want of oxygen, death from suffocation.

It is quite true that in most of these cases not only is there want of sufficient oxygen, but there is also hindrance to the output of the impure carbonic acid gas, and the retention of this gas in the body is undoubtedly a contributing cause to the death. But this added element of poisoning by accumulation of carbonic acid gas does not produce the characteristic symptoms of suffocation or asphyxia, the laboured breathing, the fight for breath. It has been proved that an atmosphere containing abundant supplies of oxygen, but also a poisonous amount of carbonic acid gas, will still produce death, but no longer attended by the symptoms of suffocation, but with the symptoms of narcotic poisoning. Headache, languor, stupor, unconscious and quiet death are now the result, not the struggle and convulsions of suffocation. To repeat, the symptoms to be described as those of suffocation are due to want of oxygen, from whatever cause that want may arise.

Symptoms.—The symptoms are best seen in all their intensity when the want of oxygen is sudden and extreme, as in drowning, choking, strangulation, and they occur in three stages. There is first the stage of dyspnœa or laboured breathing. It is a state of agitation and struggle. The movements of breathing are rapid, deep, and powerful. The ordinary muscles which produce the movements of the chest and abdomen are not only thrown into a state of intense activity, but the muscles of extraordinary respiration (p. 254) as well. The muscles between the head and chest and between the arms and chest, &c., are active, raising and pulling down the chest in the effort to get more air into the lungs. The movements of breathing are deep, prolonged, and hurried, passing into convulsive gasps for breath. This stage lasts for a minute or a minute and a half, and latterly spasmodic movements of the limbs occur. Meantime the veins of the face and surface of the body become swollen with dark-coloured blood, and the countenance is livid. In the second stage, the muscles which expel air from the lungs contract spasmodically, and this passes into a state in which nearly every muscle of the body acts convulsively, the bowels and bladder being emptied involuntarily, and general convulsions setting in. It lasts about a minute and passes into a state of exhaustion, in which the person lies still, the pupils being widely dilated; there is complete insensibility; the muscles are completely relaxed. Every now and then, however, there are a few convulsive gasps, which become weaker and feebler. Finally, a general convulsion occurs, in which the body is fully stretched out, the mouth is widely opened, and the nostrils dilated, the head is thrown back and the back straightened, and in one final effort to draw in breath the effort is over. The heart continues to beat for a few seconds longer, and at length stops in complete relaxation, when death has occurred. The whole period that elapses between the moment of complete deprivation of oxygen and death is 3 to 5 minutes. It varies in different animals; and young animals seem to be able to hold out longer than full-grown animals. At any moment in the period named, until the instant before the heart has ceased to beat, when the person is perfectly still and death seems already to have occurred, restoration is possible, if only oxygen can be introduced into the blood. The heart may still be feebly beating, even when no pulse can be felt.

The appearance of the body fully indicates the cause of death. The veins of the skin and of head and neck are gorged with dark blood;

and the face and head are swollen and turgid, and darkly purple or almost black.

All the movements that have been described are directly due to impulses to muscles from the nerve-centres, which are violently stimulated by the non-oxygenated state of the blood. They are completely beyond the control of the person, are not voluntarily made, and can occur from first to last even in a state of profound unconsciousness. The struggles thus made by a person are not, therefore, necessarily attended by pain, however painful and distressing they are to witness.

Treatment.—The perfectly clear indication for treatment is to render the admission of air to the lungs easy, if that be possible. In a case of inflammation of the lungs or of pleurisy, such as has been described, that could only be done by clearing the lungs or removing the pleuritic fluid. If the want of air be caused by blocking of the windpipe by something that has dropped from the mouth, it may be possible to remove it in the manner to be described under the head of choking. If the obstacle cannot so be removed, and if it be lodged high up, the admission of air may be rendered easy by making an opening into the windpipe from the neck, by the operation known as tracheotomy. If the person has succumbed from being in an atmosphere wanting in oxygen, removal to the outside air is the immediate step to be taken, and the loosening of the clothing about the neck and waist. If the person has been removed into pure air before the heart has ceased to beat, but when already the last stage of suffocation has been reached, and he lies quiet, making no effort to breathe, the movements of breathing may be stimulated by sudden dashing of cold water on the chest, or by flicking the chest with a wet towel. That failing, immediate effort must be made to produce artificial breathing by Sylvester's or Howard's method, described under Drowning, the preliminary step of removing water from the chest being, of course, unnecessary. In the case of children, especially, mouth-to-mouth insufflation may be practised, though Howard's method is best.

In the case of persons overcome by foul air in wells, pits, or in the recesses of quarries after blasting by gunpowder, they are to be quickly removed into fresh air, the clothing about the neck is to be rapidly unloosed, and artificial respiration practised.

Drowning means death by the air being prevented entering the lungs owing to the mouth and nostrils being immersed in a liquid, the liquid being commonly water. Death may, therefore, occur by drowning in a small quantity of water. Thus a child may fall head downwards into a tub and be drowned, though the tub is not half full of water, sufficient to cover the mouth and nostrils being all that is necessary, and a man overcome by a fit or by drunkenness may fall on a road with his head in a ditch or pool of water, and thus meet death. Death is thus due to suffocation, to the stoppage of breathing, and to the entrance of water into the lungs. When death has been caused by drowning, the skin presents the appearance called goose-skin (*cutis anserīna*), the face and surface of the body generally are usually pale, a frothy liquid is found in the lungs and air-passages, and about the lips and nostrils; water may be found in the stomach; and clenched fingers, holding substances grasped at, may serve to show that a struggle has taken place in the water, and that the body was alive at the time of immersion. Complete insensibility arises, it is probable, in from one to two minutes after submersion, recovery, however, being still possible, and death occurs in from two to five minutes. So long as the heart continues to beat, recovery is possible; after it has ceased it is impossible. Newly-born children and young puppies stand submersion longer than the more fully grown.

For the restoration of the apparently drowned several methods are suggested. Those of Dr. Sylvester, recommended by the English Humane Society, and Dr. Benjamin Howard, of New York, are the simplest, but that of Dr. Marshall Hall will also be described.

Whichever method is adopted, the following steps must first and immediately be taken: Pull the body up on to dry ground. Send immediately for medical assistance, warm blankets, dry clothing, brandy and hot water, if anyone is at hand to send. No delay must be permitted, however, in treating the person, so that if only one person is on the spot he must begin to treat the person *instantly*, without seeking assistance. Remove all clothing from the neck and chest. Fold the articles of dress removed so as to make a firm pillow, which is to be placed under the shoulders, so that the upper part of the body is slightly raised and the head slightly thrown back. Cleanse the mouth and nostrils, open the mouth and pull forward the tongue. If natural efforts to breathe are made, try to stimulate them by brisk rubbing of the sides of the chest and of the face. If no effort to breathe is made,

proceed to produce the entrance and outflow of air from the lungs by Sylvester's or Howard's method.

Sylvester's Method (Plate XVII.).—Stand or kneel behind the person's head, grasp each arm at the elbow, draw both arms simultaneously upwards till they are extended in line with the body, as a man places them when he stretches himself. Let this movement occupy about 2 seconds. This enlarges the chest and causes the entrance of air to the lungs. Without a pause carry the arms down to the sides, making them overlap the chest a little, and firmly press them on the chest. This movement should occupy other 2 seconds. It expels air from the lungs. Repeat the movements, and maintain them steadily and patiently at the rate of 15 times a minute, until breathing has been fully restored, or until medical aid arrives, or until death is certain. An hour is not too long a time to persist, and so long as there seems the least effort to breathe the efforts must be persevered in.

Howard's Method (Plate XVIII.).—Place the body on its face, with the roll of clothing under the stomach, the head being supported on the hand as shown in figure 1. Pull the body over the roll of clothing to expel water from the chest. Then turn the body on the back, the shoulders being supported as shown in fig. 2. Kneel over the body. Place both hands on the lower part of the chest, so that the thumbs hook in under the lowest ribs and the fingers are spread out on the chest. Steadily press forwards, raising the ribs, your own body being thus thrown leaning forward. This enlarges the cavity of the chest and causes air to enter. When the ribs have been raised to the utmost extent, with a slight effort push yourself back to the more erect position, allowing the ribs to recoil to their former position. This expels the air. Repeat the process 15 times a minute. One person will find it more easy to maintain this method for a prolonged period than Sylvester's, especially if the patient be big and heavy.

Meanwhile, if other persons are present they should be occupied rubbing the body and limbs (*always upwards*) with hands or warm flannel, applying hot flannels, bottles, &c., to the limbs, feet, arm-pits, &c. As soon as the person is sufficiently restored to be able to swallow, give small quantities of hot brandy and water, hot wine and water, hot coffee, &c., and use every effort to restore and maintain warmth.

Marshall Hall's Method.—After clearing the mouth and throat let the operator kneel on one side of the patient, who is placed on his back with the arm opposite the operator close down against the side, a folded coat or other article of dress being under the back. From this position let the operator turn the body up, away from him, on to the side and slightly farther so that the chest looks to the ground, and in this position let the operator press firmly on the side and back. This compresses the chest on the under arm, and expels the air. Let the pressure be removed and roll the patient slowly on to his back again. The chest expands slightly and the air enters. These movements are to be repeated steadily and regularly, about fifteen times a minute, once every four seconds. If another person be present let him attend to the movements of the head to keep it in line with the body as it is turned. The movements of the chest are not nearly so pronounced by this method as in Sylvester's or Howard's, but one man can perform them for a long time. This advantage is also possessed by Howard's method, which in addition causes much greater movement, and is, therefore, to be preferred.

Choking is caused by something slipping down from the mouth and blocking, more or less completely, the upper part of the air-passage. A portion of food may do this, or a coin, or other article which has been held in the mouth. Besides the sudden obstacle to breathing, there is commonly violent spasmodic cough due to irritation of the air-passages by the presence of the foreign substance, which may ultimately cause expulsion of the substance. Sometimes a mass of food will stick in the upper part of the gullet, causing violent effort to swallow or expel it, without at the same time seriously impeding the passage of air. But the feeling of its presence causes great agitation to the person, especially a child or young person, from the fear of suffocation. One must not mistake this state of terror for a state of threatened suffocation. In such cases one can easily perceive that there is no blueness of the face, no swollen state of the veins of the skin, and that the breath can be drawn in and expelled with comparative ease and fulness. The patient must be calmed, assured that there is no danger, and steps may then be quietly taken either to push the mass down into the gullet or to hook it out with the finger. The author remembers vividly a young man who had been eating a sandwich, a bite of which had stuck not at the back of the throat at all, but in the gullet, a short distance down. Owing to its

position it pressed forward on to the box of the windpipe in front, and produced the sensation of being in the upper part of the windpipe. The youth was in such a state of excitement and alarm as to make it difficult to assist him. His face, however, but for his terrified appearance, was natural and his breathing free. He was ordered to keep still, and to notice with what ease he continued breathing; and he thus became aware that no serious danger existed. He realized that he was quite safe from risk of suffocation, became quite quiet, and without further trouble a stomach-tube was passed down the gullet and the offending mass pushed safely into the stomach. But if the face becomes quickly swollen and livid, it is clear that suffocation is near, and immediate steps must be taken to avert it. Let the mouth be widely opened and kept from closing by something placed between the teeth, a thick cork, a piece of wood. This is necessary, to prevent the operator's finger being bitten. Then let the operator pass his forefinger through the mouth to the back of the throat. The finger should be passed in away to the side, the cheek being stretched as much as possible. This enables the finger to reach well down the throat. The finger is then swept round the throat in search of the obstruction, which it removes by being insinuated behind and beneath it. If this failed to relieve the person, a surgeon would open the windpipe by the operation of tracheotomy (p. 270), an operation which, in cases of simple obstruction, would relieve even at the very last moment. In the case of children the obstruction may sometimes be dislodged by holding the child up by the heels and smartly slapping the back between the shoulders with the flat of the hand.

In many cases where the breathing is much obstructed swallowing is still quite easy, and the expulsion of the obstacle may be effected by the action of vomiting. This is induced by a tea-spoonful of mustard in a tumbler of tepid water, or by copious draughts of lukewarm water, or by tea-spoonful doses of ipecacuanha wine.

Should ordinary measures fail, should a surgeon not be obtainable in time, is the person to be allowed to die because no skilled assistance is at hand? Surely not! In such an emergency let some person, sufficiently cool and collected, take a pair of sharp fine-pointed scissors, perfectly clean. The scissors must not be too thin in the blades. Lace scissors are too fine. Let him grasp them firmly, *closed*, in his right hand, extending the right forefinger along the *closed* blades to within ⅝ths of an inch of their points, and keeping it firmly pressed there to act as a stop. Let the patient be stretched out flat on his back, head thrown back, and let the operator lay his left forefinger on the front of the neck, just under the chin, and carry it down the front of the neck in a straight line till he feels the upper border of the larynx —Adam's apple. Let him carry his finger down the middle line of this prominence, pressing his finger point firmly on it, and a little way down his nail will slip into a little oval space between the lower edge of this upper part of the box of the windpipe and the succeeding gristly ring, the space marked o in Fig. 134, p. 262. At this point, only the skin and fatty tissue beneath it and a thin membrane covering over the space are interposed between the fairway of the windpipe and the outside. Keeping the left forefinger firmly pressing on this place to mark its exact site, an act attended with a little difficulty, for the box of the windpipe will be violently forced up and down with the convulsive efforts to breathe, the operator steadily pushes the scissor points through skin and membrane till they penetrate into the windpipe; the right forefinger acting as a stop ensures that they are not passed too far. The instant they have penetrated, a hissing noise, the noise of issuing air, will proclaim the fact, along with some frothy and bloody fluid. But the person must not be alarmed. He must, then, slowly separate the blades of the scissors, so as to enlarge the wound and keep it open, doing so until the air enters and issues freely. He must keep the scissors steadily in that position, being on guard lest they slip out owing to a convulsive cough or heave of the patient, or lest they be accidentally thrust farther in; and in this position he must keep them till a surgeon arrives. If struggle has ceased before the scissors have opened into the windpipe, and no effort of breathing be made by the patient, someone else must practise artificial respiration while the operator keeps the wound open. With no one to help him, the operator might yet keep the scissors in position with one hand and, by pressing heavily on the chest with the other and then removing the pressure, produce respiration to some extent.

If a coin has slipped into the windpipe it will commonly not completely block the passage, so that the necessity of extreme haste is not so great. But it produces violent spasms of coughing whenever it comes up near the box of the windpipe. Place the person flat on a

RESTORATION OF THE APPARENTLY DROWNED OR SUFFOCATED.

SILVESTER'S METHOD

Plate XVII

The movement by which air is made to enter the lungs.

The movement by which air is expelled from the lungs. The double movement should be carried on regularly at the rate of 15 times per minute and should be persisted in for an hour where the slightest hope of restoration exists.

couch which is easily lifted. Let someone hold him there so that he will not slip off, and let another suddenly lift the foot end high up so that the head is quickly brought to a low level. The coin may roll down the windpipe and out by the mouth. If not it will tickle the larynx and produce the storm of coughing. Bring the couch down to the horizontal, and, in a little time, repeat the manœuvre. If after patient effort this fails, an operation for extraction of the coin by opening the windpipe will be necessary.

Hanging, when there is no marked drop, produces death by suffocation. In the case of hanging as a capital punishment the noose is so arranged, and the length of drop so proportioned to the weight of the individual, that the sudden jerk, produced when the bolt of the platform on which the condemned man stands is drawn, causes dislocation between the first and second vertebræ of the neck and consequent destruction of the nerve-centres presiding over the action of the heart and lungs, so that death is instantaneous and with little or no struggle. But when a person hangs himself, death is by strangulation, the pressure of the rope compressing the windpipe. If any indications exist to suggest that a person found hanged is not quite dead, he should be immediately cut down and the noose unloosed or cut. The fingers and thumb grasping the windpipe where the pressure has been may re-establish the fairway of the tube if the pressure has obliterated it. Then artificial respiration should be performed by Howard's or Sylvester's method, friction should be applied or hot sponges over the heart, and if the patient revives some warm stimulant given.

Strangulation by whatever means is to be treated as directed for Hanging.

SECTION VI.—WHAT TO DO IN CASES OF POISONING.

Classification of Poisons:
Corrosive and Irritant, Narcotic, and Narcotico-irritant Poisons.
Symptoms of Poisoning:
Symptoms of Corrosive and Irritant Poisoning;
Symptoms of Narcotic Poisoning;
Symptoms of Narcotico-irritant Poisoning.
General Treatment of Poisoning:
Emetics and Antidotes.
Corrosive and Irritant Poisons:
Acid Poisons—Hydrochloric, Nitric, Sulphuric, Carbolic, Acetic, and Tartaric Acids;
Poisoning by Caustic Alkalies—Soda, Potash, Saltpetre, and Ammonia;
Metallic Poisons—Antimony, Arsenic, Lead, Mercury, Tin, Zinc;
Poisoning by Iodine and by Phosphorus and Lucifer Matches.
Poisoning by Alcohol.
Narcotic and other Nerve Poisons:
Opium and Morphia Poisoning;
Chloral Hydrate and Chlorodyne;
Hydrocyanic or Prussic Acid;
Aconite Poisoning;
Atropine and Belladonna Poisoning;
Calabar Bean (Physostigmine), Cannabis Indica (Indian Hemp), and Stramonium (Thorn-apple);
Nux-vomica and Strychnine Poisoning; Poisoning by Paraffin-oil.
Poisoning by Vegetable and Animal Irritants:
Aloes, Castor-oil Seeds, Croton-oil, Colocynth;
Elder Leaves and Flowers, Gamboge, Hiera-picra, Podophyllum;
Arum maculatum (Lords and Ladies); Camphor; Cantharides (Spanish-fly);
Cocculus Indicus;
Digitalis; Hellebore, Veratria, and Sabadilla;
Hemlock Poisoning;
Laburnum; Lobelia (Indian Tobacco);
Meadow Saffron (Colchicum); Nightshade; Privet Berries; Pulsatilla and Poke Berries;
Tobacco; Turpentine; Virginia Creeper; Yew Berries;
Poisonous Clothing, Wall-papers, Hair Dyes, and Cosmetics.
Poisonous Food.

Classification of Poisons.—Poisons are substances which are capable of acting injuriously on the body and destroying life, either by their direct chemical action on the part to which they

are applied, whether external or internal, or indirectly by gaining access to the circulation and acting on the various tissues and organs of the body. This is a very broad way of putting it, but poisons are so numerous and their effects so diverse that it is not easy to define very strictly what a poison is. The Greek word for poison is *toxicon*, and the poisonous effects of a substance are called its toxic effects, while *toxicology* is that special department of science which makes poisons and their effects its study, a toxicologist being one engaged specially in such work. The general definition which has been given of a poison embraces many substances not readily occurring to one's mind when the word poison is used. It includes substances not generally thought of as poisons when used in an ordinary way. Thus alcohol is a poison within the scope of the definition, though it only becomes so when used beyond certain limits. But then the dose has nothing to do with the inclusion or exclusion of any substance, for while a single drop of pure prussic acid will cause death, and the $\frac{1}{20}$ of a grain of aconitine, the active principle of aconite (monkshood), 60 drops is the smallest quantity of laudanum known to have caused death in an adult. Then the general definition allows room for the old adage, "What is one man's meat is another man's poison." Certain articles of food act constantly on some people like irritant poisons, notably shell-fish, but also other quite ordinary kinds of food, such as mutton and eggs; and there are now included as poisons certain substances produced in animal food kept for a long time excluded from the air. The exact nature of these substances has not been determined, but the term *ptomaines* has been applied to them, from Greek *ptōma*, a dead body, since it is dead animal matter in a state of decay in which they are produced. Many instances of poisoning arising from the eating of tinned meats are attributed to the production of these substances, not to the introduction from without of any injurious substances. Owing, therefore, to the diverse character of poisons there is some difficulty in arranging a suitable classification. One might consider their chemical constitution and arrange them accordingly, for example into those belonging to the class of inorganic substances, and those belonging to the class of organic substances. The inorganic substances might be further subdivided into poisonous gases, such as carbonic acid gas, carbonic oxide, sulphuretted hydrogen, &c.; acids, such as nitric, sulphuric, hydrochloric; metals, such as lead, arsenic, mercury, antimony; and non-metals, such as phosphorus. Belonging to the organic class are opium, chloral, alcohol, prussic acid, strychnine, belladonna, which it would be difficult still further to subdivide. It is clear that any such classification would be of no practical use. If poisons could be arranged into well-defined groups, according to their effects upon the body, each poison of one group exhibiting more or less similar symptoms to the others of the same group, and similar treatment being required for all the poisons of one group, then such a classification would be of the greatest possible benefit, because it would simplify the recognition of the kind of poison used in any particular case, and a knowledge of the principles of the grouping would be almost equivalent to a knowledge of the mode of treating any cases that might arise. Such a classification has been attempted, but only in a very general way, for the great diversity of action of the different poisons makes it impossible to effect it more accurately. Moreover, marked differences in the effects one and the same poison produces on the body are observed corresponding to the quantity of poison administered, its state of concentration or dilution, and the condition of the individual at the time of partaking of it. For example, the mineral acids given in their concentrated form produce, immediately on being swallowed, painful burning sensations in mouth, gullet, and stomach, and by their powerfully corrosive action destroy the tissues with which they come into contact, so that death speedily arises, while one of the same acids given largely diluted would have none of these caustic effects, though remote effects on other organs might follow. Then again, the same dose of one poison, oxalic acid, for example, if given in concentrated solution, will produce signs of irritation and inflammation of the mouth, gullet, and stomach; but if given diluted with a large quantity of fluid or other liquid will produce no such symptoms, but in a brief time will cause death through its effects upon the heart and nervous system. If, then, we indicate a grouping of poisons according to their effects upon the body, it must be understood that such a classification is not by any means complete. This classification is one commonly used, and it includes at any rate the most of the poisons commonly known; it is the grouping into the two classes of **irritant or corrosive poisons and narcotic poisons.** Irritant poisons are those which set up irritation or inflammation of the throat, gullet, stomach, and bowels, which irritation is readily recognized by the symptoms

THE RESTORATION OF THE APPARENTLY DROWNED.

HOWARD'S METHOD

Plate XVIII.

The person is pressed face downwards over the clothes, rolled in a bundle and placed under the stomach, for the purpose of expelling any water that may have entered the stomach or lungs.

In the second position the rescuer spreads his hands over the under ribs, and pushing upwards, causes the chest to expand and air to enter the lungs. He then springs back into the upright kneeling posture and thus allows the chest to return to its former position, and the air to be expelled from the lungs. This movement should be repeated regularly 15 times per minute.

about to be described; and narcotic poisons are those which act upon the nervous system, inducing paralysis of the brain, insensibility, stupor, and death.

Symptoms of Poisoning.—Stevenson says that the general symptoms which should excite a suspicion of poisoning are the sudden onset of serious and increasingly alarming symptoms, in a person previously in good health, especially if a prominent symptom be pain at the pit of the stomach; or where there is complete prostration of the vital powers, a cadaverous expression of the countenance, an abundant perspiration, and speedy death. Now we have not quoted these sentences from Stevenson in order to indicate that, when such symptoms arise, the unskilled person is immediately to jump to the conclusion that poison has been at work, but rather as a warning against the coming to such a hasty conclusion. For all these general symptoms that have been noted may arise, and do arise, in cases of natural disease. One has known a man, for example, suddenly seized with intense pain at the pit of the stomach while he was actively engaged, apparently in good health, in the transaction of business. Great pallor, most alarming prostration, immediately occurred, and his countenance bore a look of intense anxiety. Unable to assist himself to the slightest degree, he was conveyed home, and was dead fifteen hours later, having never recovered the state of collapse into which, all in an instant, he was plunged. Now, anyone who had read the sentence, in which have been noted the general symptoms, which should excite suspicion of poisoning, would say, "Here surely is a case which accurately answers to the description—this man must have been poisoned." But no such suspicion ever occurred to anyone. The explanation of the whole case was that the man had suffered from a chronic ulcer of the stomach, of which, however, there had been almost no symptoms, so that he thought himself in average health, but it had gradually burrowed its way through the coats of the stomach; and on the day in question he suddenly slipped his foot, made a quick, strong effort to recover himself, and the sudden strain caused rupture of the ulcer—a tear of the stomach wall—to occur, and to be followed by extensive bleeding, of none of which, however, was there any external sign. The sudden pain was at the moment of rupture, and the intense prostration was the result of the internal bleeding. We wish, therefore, to emphasize as strongly as possible the fact that natural diseases present symptoms utterly indistinguishable in many cases from those of poisoning, at least utterly indistinguishable to an unskilled person, however much aided by the reading of descriptions and the study of authorities. Nay, in many cases it is quite impossible for a medical man, however skilled, to distinguish with certainty between natural disease and poisoning. Whenever his suspicions are aroused, he seeks other evidence, evidence from circumstances in the surroundings of the patient, and chemical evidence derived from examination of vomited matters and so on. Illustrations of this fact could be indefinitely multiplied. In a recent case, which excited great public interest, the evidence of medical experts, experts on the subject of poison, was equally emphatic on both sides of the case, the one maintaining all the symptoms were those of poisoning by arsenic, the other that they were no more than symptoms of inflammation of stomach and bowels. Let no one, therefore, come to hasty conclusions as to the causes of an illness, still less be unwise enough to utter suspicions aloud. If symptoms seem to be suspicious, rather let expert medical aid be immediately summoned, and let the person communicate privately, if need be, to the doctor any painful surmises that may have been aroused.

The symptoms of the two common kinds of poisons—irritant and narcotic—will, if now given, be a sufficient general indication of the nature of symptoms of poisoning; and special symptons will be given in detail in speaking of special poisons, later in the section.

Symptoms of Irritant and Corrosive Poisoning.—The symptoms of irritant poisoning are due to the caustic or burning effect of the poison on the mucous membrane of the parts with which it comes into contact, the lips, mouth, throat, stomach, and bowels—if it reaches that length; and the effects are due to the immediate chemical action of the substance. There is a hot, acrid, burning pain and sense of constriction on lips, mouth, throat, and gullet. The feeling of burning from the gullet downwards to the stomach is very great, and thirst is intense. In the stomach there is a sharp burning pain, which extends more or less all over the belly, and pressure on the surface of the belly produces a feeling of tenderness, and speedily of actual pain. The pain of colic is relieved by pressure. Vomiting occurs, usually quickly, and the vomited matters increase the acrid sensations in the gullet and mouth. At first the material vomited is simply the contents of the stomach, but as the vomiting persists the

material becomes bilious and mucous, and later may contain blood, which, however, may not be red in colour, but brown or black by the action of the contents of the stomach. The pain over the belly rapidly increases, and the belly becomes swollen, so much sometimes as to make breathing difficult. The vomiting may be followed by purging, if the poison has reached the bowel, and the motions are watery, frequent, accompanied by painful cramps, and perhaps containing blood. The urine is scanty, passed with pain and difficulty, or not passed at all. If the action of the poison has been quick and powerful the patient may show speedy signs of collapse, in weakness and rapidity of pulse, in short shallow breathing, in cold clammy skin and pinched features; and death may occur in from six to twenty-four hours. If the action of the poison has been less immediately and powerfully active, a stage of inflammatory fever, with flushed face and bounding pulse, may precede the stage of collapse and sinking.

The symptoms vary more or less in detail according to the actual poison. To the class of irritant poisons belong:—

Sulphuric Acid (Oil of Vitriol).
Hydrochloric Acid (Muriatic Acid, Spirit of Salt).
Nitric Acid.
Carbolic Acid.
Oxalic Acid.
Creasote.
Caustic Potash.
Caustic Soda.
Caustic Lime.
Caustic Ammonia.
Arsenic.
Antimony.
Copper.
Lead.
Mercury.
Phosphorus.
Silver.
Zinc.
Croton-oil.
Elaterium.
Gamboge.
Spanish-fly (Cantharides).

While all of these are irritant some are, besides, powerfully corrosive, all the acids, for example, the caustic soda, potash, lime, and ammonia, and corrosive sublimate—a preparation of mercury. In strong solutions they produce immediately destruction of a layer of the mucous membrane of lips, mouth, &c., more or less deep, which is quite visible to the naked eye. In the case of nitric acid it is a yellow stain, in the case of sulphuric it is white, and whitish or brown in the case of hydrochloric; that of carbolic acid is white, while caustic potash and soda produce a white drawn appearance. Nitric, hydrochloric, and sulphuric acids produce also yellow, red, or brown stains on the clothing, when any has dropped upon it. The acids and other caustic substances may be dilute enough not to produce such scars, but yet to occasion the irritating effects, and in the case of the metallic poisons it is the irritating effects alone that are pronounced. In the case of the marked corrosive effects being produced, shreds of the destroyed mucous membrane are vomited with blood more or less altered.

The diseases which are apt to be mistaken for poisoning from such substances are inflammation of stomach and bowels, ulcer of stomach and bowels, colic, and cholera; but when a corrosive substance has been swallowed the marks on lips, mouth, and throat will clear up the nature of the case.

When recovery from the immediate effects of the poison occurs, death may yet ensue from subsequent ulceration and exhaustion, or from constriction of gullet and stomach, resulting from the destruction wrought by the poison and the subsequent process of healing.

The Symptoms of Narcotic Poisoning are best seen in the case of opium, morphia, or laudanum poisoning, where there are drowsiness, passing on to deep insensibility, snoring breathing, livid countenance, cold clammy skin. In some cases—poisoning from belladonna and henbane, for example—there is delirium.

The chief narcotic poisons are:—

Alcohol.
Belladonna.
Chloral Hydrate.
Chloroform.
Conium.
Digitalis.
Hyoscyamus or Henbane.
Indian Hemp (*Cannabis Indica*).
Morphia, Opium, and their preparations.
Prussic or Hydrocyanic Acid.
Stramonium (*Thorn-apple*).

A third set of poisons has been called **narcotico-irritant**, because they produce effects similar to both irritants and narcotics. They excite vomiting and purging like the former, but the symptoms go on to stupor, unconsciousness, convulsions, or paralysis. To this class belongs a very large number of vegetable poisons, including croton-oil, colchicum, laburnum, woody nightshade, and many other substances belonging to the vegetable kingdom, including muscarin, the poisonous active principle of poisonous mushrooms.

Poisons, developed in preserved food, are of this class, the sickness, vomiting, purging, weakness, and exhaustion which arise, some time after the food has been taken, yielding subsequently to symptoms indicating action on the brain and nervous system.

The Treatment of Poisoning.—Later in this section, and under the head of each poison, the appropriate treatment in detail for each kind of poison will be given separately, but it will be well to indicate here the general principles of treatment common to all cases. If the poison has been swallowed it passes into the blood from the stomach. Clearly if it can be removed from the stomach before it has had time to be absorbed into the blood, much of the risk will be removed. There are two ways of doing this:

By the use of the stomach-pump,
By substances which cause vomiting—emetics.

In every case, almost without exception, the removal of the poison from the stomach is the first thing to be done. If treatment be begun immediately after the poison has been taken, this may be so effectual that not the slightest sign of poisoning may arise. The author once had to deal with a woman who had drunk the whole contents of a sixpenny packet of rat-poison (arsenic), and who immediately thereafter confessed what she had done. Treatment was begun within 10 or 15 minutes thereafter, and so effectually was the stomach washed out that not the slightest symptom of any disturbance whatever appeared.

The **stomach-pump** is commonly only in the hands of a doctor, and need not be described in detail here. It consists of a long gum-elastic tube, about the thickness of one's finger. It is passed through the mouth into the throat, being directed well back, and down the gullet to the stomach. A small pump is fixed at the mouth end, and water injected till the stomach is well filled, when, by means of a flute-key arrangement, the action of the pump is reversed, and the stomach emptied again. A single-action pump, however, is not unsuitable, which permits the stomach to be filled but has no arrangement for reversing the action without unscrewing the pump portion. The stomach can, however, be washed out by a much simpler contrivance, a simple gum-elastic tube to which a funnel can be attached at the outer end, and water thus run into the stomach. If, when the tube is full, the end is closed to keep it so, and then bent downwards sufficiently, and the end allowed to open, the tube will act as a syphon and drain off the water till the stomach is empty. The outer end of the tube should then be raised, the funnel adjusted, and the stomach filled again, and afterwards again emptied. For it is not enough to empty the stomach, it should be washed out to prevent any portion of the poison being left adherent to the stomach walls to be afterwards absorbed. In an emergency a stomach-tube can be easily devised out of 6 or 8 feet of ordinary thick india-rubber tubing. It is passed down into the stomach, and a funnel attached to the outer end as already indicated. If no filler can be had the ivory end of a syringe could be attached to the outer end of the tube, and by working the syringe the water can be injected into the stomach.

The only cases in which it is not allowable to use the stomach tube or pump are those in which corrosive poison has been swallowed, as there is great probability of some parts of gullet or stomach being so softened or destroyed that there is risk of the tube being pushed through the wall.

As to **emetics**, a great variety may be used. Those almost always at hand are salt and water, and mustard and water:—two table-spoonfuls of common salt in a tumblerful ($\frac{1}{2}$ pint) of tepid water, or a dessert-spoonful of mustard in a tumbler of water. If that is not effectual in a few minutes it may be repeated. The other common emetics are:

30 grains Sulphate of Zinc in a little water,
30 grains Ipecacuanha Powder in a little water,
2 table-spoonfuls of Ipecacuanha Wine in a little water.

The mustard and water may be given first, the mustard being stimulating besides causing vomiting, and it could be followed immediately by a mixture of 30 grains sulphate of zinc and 30 of ipecacuanha powder. Any one of these is quite safe in the hands of an unskilled person, but tartar emetic or antimonial wine should not be resorted to by inexperienced persons. (Emetics are considered in detail on p. 850.) In the absence of any of these substances copious draughts of warm water are to be given, tumblerful after tumblerful, till vomiting occurs. The throat may be tickled with a feather, or the finger passed down to excite retching.

The second thing to do in cases of poisoning is to endeavour to neutralize any direct chemical effect which the substance might have on the stomach walls. In the case of acids this is done by giving draughts of alkaline substances in water, bicarbonate of soda or potash, magnesia, chalk, whiting, plaster from the wall; and, in the

case of caustic potash or soda, vinegar in water, lemon juice in water, &c. It is well not to give the neutralizing substances in great quantities all at once, else the enormous development of gas which would occur might be hurtful, especially if any part of the walls of the digestive canal had been seriously damaged by the poison, but in small quantities frequently repeated.

A third step to take is to protect the walls of the stomach as far as possible from the action of any irritating agent, by drinking freely of bland fluids, like white of egg beat up in water, gum and water, oil, milk, &c.

All these steps have for their object protection of the mucous membrane from direct action of the poison. But if the poison has been taken some time before treatment was commenced, some of it must be already absorbed into the circulation, and will not be reached at all by these measures. Nevertheless even though the poison has been taken some time before, it is well to empty and wash out the stomach, in one way or another, for although the whole of it cannot be recovered, it may not be all absorbed. Some of it may yet be lurking about the coats of the stomach, and if allowed to remain will gradually be absorbed, intensifying all the symptoms. The stomach, therefore, ought always to be washed out to prevent this. Again, there are many ways in which poison may gain entrance to the body besides by the mouth and stomach. The poison may have gained entrance by the skin, it may have been rubbed in with liniment or ointment, or it may have gained entrance by a wound, or it may have been administered by hypodermic injection. In all these cases cleaning out the stomach can have no effect on the poison already circulating in the blood. For such cases it is necessary to employ an antidote, if an antidote be known for the particular poison.

Antidotes (Greek, *antidotos*, a remedy) are substances which counteract or prevent the action of a poison. This they may accomplish in the stomach before the poison is absorbed. Thus if snake poison be mixed with a solution of permanganate of potash, it ceases to have any poisonous effect; if white of egg and corrosive sublimate (perchloride of mercury) be mixed, an albuminate of mercury is formed, which is insoluble and cannot be absorbed; arsenic and iron form an insoluble compound, and so a solution of freshly prepared oxide of iron is given in arsenical poisoning. In such cases it becomes necessary to wash out the stomach, after the antidote has been given, to expel the now insoluble poison. But some antidotes also act by producing on the various organs of the body effects which counteract those produced by the poison. Substances are, therefore, given which follow up the poison in the blood and prevent it producing its usual results. Substances which thus hinder one another's effects are said to be **antagonistic drugs.** Thus belladonna is an antidote against opium poisoning, and, of course, opium to belladonna poisoning, chloral hydrate is to some extent an antidote to strychnine. In cases of poisoning, then, besides washing out the stomach, or exciting vomiting, giving substances to neutralize any corrosive action, supplying bland and soothing substances to the stomach, it is necessary to administer, if possible, an antidote to the poison.

Besides the various steps that have been related, others must be taken, varying according to the circumstances of the case. The person should be kept warm by means of warm clothing, warm rubbing, &c. If shock has been produced, if the heart and breathing are feeble, the skin cold and pale, the general treatment described under Shock, p. 990, must be undertaken. Again, if the person be drowsy, every effort must be made to arouse him—douches of cold water are useful for this purpose, stimulants may be necessary, and commonly are. Hot coffee is one of the best, but hot alcoholic stimulants may be advisable.

POISONING BY CORROSIVE SUBSTANCES—ACIDS — CAUSTIC ALKALIES — LUNAR CAUSTIC—IODINE AND PHOSPHORUS.

Poisoning by Corrosive Acids.—These acids are:—

Hydrochloric Acid or Spirit of Salt or Muriatic Acid,
Nitric Acid or Aqua Fortis,
Sulphuric Acid or Oil of Vitriol,
Carbolic Acid, Phenic Acid or Phenol,
Acetic and Tartaric Acids.

The symptoms of poisoning by these acids have been already described under irritant poisons on p. 1015. They are, briefly, immediate burning pain in mouth, gullet, and stomach, great thirst, vomiting of intensely acid material, the food vomited being mixed with altered blood. Inflammation of the bowels arises and the belly becomes swollen and tense. There is likely to be constipation and suppression of urine. The stain in the mouth is yellow in the case of nitric acid, brown in the case of hydrochloric, and white in the other cases. The shock is marked

by weak pulse, and cold clammy skin; difficulty of breathing and swallowing are marked. In the case of carbolic acid the urine becomes dark, even black in colour. A similar dark-coloured urine is sometimes passed in surgical cases, owing to absorption of the carbolic acid used for the dressings, but it is not usually attended by other symptoms.

In the case of each of the strong acids one to two tea-spoonfuls can prove fatal, but recovery has followed the taking of even half an ounce.

Treatment.—(1) Do not attempt to use the stomach-pump, nor to induce vomiting; the damage to the parts may be so great that this would be accompanied by risk.

(2) Give immediately large quantities of water to dilute the acid, containing also some alkaline material to destroy the acid. Soapy water, water with bicarbonate of potash, bicarbonate of soda, common washing soda, magnesia, ammonia, chalk or lime water, whatever of this kind is at hand, will suit.

(3) Follow up this with bland drinks which will soothe the corroded membrane, white of egg drink, gummy water, milk, oil freely, and so on.

(4) Maintain the warmth of the body, restore the patient from shock (see p. 990), and subsequently give nourishing and stimulating food.

In the case of carbolic acid Epsom salts or Glauber's salts are to be given—½ ounce in ½ pint of warm water. They form sulpho-carbolates with the acid, which, though absorbed, are harmless. Large quantities of Epsom salts or Glauber's dissolved in tepid water may be used to wash out the stomach, and the other treatment is the same.

Oxalic Acid Poisoning.—Oxalic acid or the oxalate of potash—salts of sorrel—is sometimes taken by mistake. It produces symptoms identical with those of the corrosive acids named, and it may cause death within ten minutes of its being taken. Besides the corrosive effect it has a powerfully depressing action on the heart, causing feeble pulse and excessive languor, and it is these nervous effects that cause the speedy death.

A quarter of an ounce has killed, but recovery from twice that quantity has occurred.

Treatment.—(1) Give freely chalk, lime, or whiting. The lime or whitewash from walls may be used, lime-water also, or tea-spoonful doses of the saccharated solution of lime frequently repeated. These lime preparations form insoluble salts with oxalic acid, but soda, potash, magnesia, ammonia form soluble salts, and are to be avoided.

(2) Give an emetic to clear out the stomach after the lime draughts.

(3) Clear out the bowels with an ounce of castor-oil.

(4) Maintain warmth; and supply stimulants, if necessary.

Acetic Acid.—Glacial acetic acid would cause corrosion like the acids already named. Cases of poisoning are to be treated exactly as those of the other acids.

Tartaric Acid has been taken in mistake for a saline medicine, and one ounce of it has caused death. The symptoms are great pain in the abdomen, convulsions, collapse, and death.

Treatment.—Large draughts of water containing lime, whitewash, or whiting should be given, or tea-spoonful doses, frequently repeated, of saccharated solution of lime. Soda, potash, and ammonia are to be avoided. The bowels are then to be cleared out by a full dose of castor-oil.

Poisoning by Caustic Alkalies (Soda and Potash).—Solutions of these caustic substances are sometimes taken by mistake. The impure carbonate of potash—pearl ashes—used for cleaning may be accidentally taken, and caustic lime may be similarly swallowed. In such cases loose stools, purging, bloody motions are the rule, while in the case of acids it is constipation. Otherwise the symptoms are similar to those produced by corrosive poisons.

Treatment.—(1) Do not use the stomach-pump, but give copious draughts of water, vinegar and water, acetic acid in water, orange lemon or lime juice, citric or tartaric acid in water, and so on, to neutralize the soda or potash, and give such in small quantities frequently repeated—repeated every few minutes.

(2) Subsequently give the bland drinks of gummy water, white of egg drink, olive-oil, &c., as directed for acids.

Saltpetre or Nitre (*Nitrate of Potash*) may cause fatal poisoning in a one-ounce dose. The symptoms are those of an irritant poison, with subsequent tremors, convulsions, and death from collapse. In this case use the stomach-pump or an emetic, and then use warmth and stimulants to ward off the shock, giving bland drinks also as before.

Ammonia, in addition to producing effects akin to caustic alkalies, acts upon the lungs and air-passages, producing suffocative cough, often

loss of voice, and sometimes death by the irritation of lungs and air-tubes. In addition to the treatment advised for soda and potash, employ inhalations of steam. An operation may be necessary to relieve the breathing if the swelling at the top of the windpipe be very great.

Lunar Caustic sometimes accidentally passes down into the stomach when being used for touching an inflamed throat. It is a preparation of silver—nitrate of silver, but it may be well to consider it here, alongside the other caustic substances. Symptoms of irritant poisoning are produced, pain, vomiting, &c., and the vomited matter is of a flaky white appearance, and turns brown or black on exposure to light.

Treatment.—(1) Give large draughts of common salt dissolved in water. This forms with the caustic the insoluble chloride of silver.

(2) Then give an emetic, ipecacuanha (20 grains), sulphate of zinc (20 grains) or mustard in water, to empty the stomach.

(3) Soothing drinks, oil, gummy water, white of egg in water, barley-water, are then to be supplied.

Iodine, a non-metallic element, occurring in crystalline scales, may be most conveniently considered in this group. It may be taken in the form of the scales, by mistake for another substance, or as the solution—tincture of iodine. Symptoms of irritant poisoning are produced, and faintness, giddiness, and convulsions may occur. Iodine strikes a blue with starch, and the vomit may consequently be blue.

Treatment consists in (1) the use of the stomach-pump, or an emetic of mustard (table-spoonful) in a tumbler of water, or 20 grains of sulphate of zinc or ipecacuanha powder in water.

(2) Give freely drinks of starch and water, arrow-root, white of egg, gruel.

(3) Apply poultices over the stomach to relieve pain.

The effects produced by excessive doses of iodide of potassium are called **iodism**, and are described on p. 825.

Phosphorus poisoning may arise from the solid phosphorus, from the use of rat paste—phosphorus paste—in children from the sucking of lucifer matches; and chronic cases are frequent from the inhalation of phosphorus fumes in match manufactories.

Symptoms of irritant poisoning, colicky pains, vomiting, diarrhœa may be more or less marked. The vomited matters, sometimes the urine, are luminous in the dark; and the breath has a peculiar garlicky odour. The liver is specially affected, is tender, and enlarged, and in a few days jaundice occurs; the urine is scanty, high-coloured, and contains bile. There may be bilious vomiting; there is headache; and the patient is dull and sleepless, perhaps in muttering delirium, with weak, fast pulse, death occurring in from two to ten days of exhaustion. The dose which will produce such effects is about ½ grain. Sometimes there is a marked tendency to bleeding, the vomit and stools being bloody, bleeding from the nose occurring, and bleeding taking place in the skin producing the appearances of bruising. In other cases nervous symptoms are most pronounced, mental failure, prostration, convulsions, and stupor. One marked result in chronic cases is decay of the teeth, and death (necrosis) of the lower jaw-bone.

Treatment.—In acute cases (1) give an emetic of 20 grains powdered ipecacuanha or sulphate of zinc in water.

(2) Give 10 to 20 drops of oil of turpentine, frequently repeated (every half hour for a time)—the French oil of turpentine specially.

(3) Give ½ oz. Epsom salts as a purge.

(4) Administer in plenty gummy drinks, *but no oils,* as they dissolve the phosphorus and make it more readily absorbed.

Poisoning by Lucifer Matches is to be similarly dealt with.

METALLIC POISONING.

The metals which most frequently give rise to cases of poisoning are:—

Antimony,
Arsenic,
Copper,
Lead,
Mercury.

The symptoms they produce are generally those of an irritant poison (p. 1015).

Antimony—Tartar Emetic.—Tartar emetic produces speedy and violent vomiting, and poisoning by one large dose is comparatively rare, since the expulsion of the poison from the stomach is quickly secured. The vomit is at first of food; then it becomes bilious, and finally tinged with blood. There is pain in the abdomen; a metallic taste is felt in the mouth, and a burning pain and feeling of constriction, extending to the throat and gullet. Just preceding

the vomiting there is intense prostration, and faintness, accompanied by weak pulse and feeble breathing, while the skin is cold and bathed in a cold perspiration. Later the bowels become affected and a copious watery discharge comes from them, resembling the rice stools of cholera, while the urine becomes scanty and may be suppressed. The patient is excessively weak, muscles are relaxed, and cramps of the extremities sometimes occur.

A single large dose may or may not prove fatal according to the rapidity with which vomiting occurs. But recovery has occurred after half an ounce had been taken, though 10 to 20 grains would likely cause death in a few hours; and 2 grains have proved fatal; while three-quarters of a grain have killed a child.

Much smaller quantities than those named will cause death if they are given in small frequently-repeated doses. Similar symptoms occur—prostration, sickness, vomiting, purging, profuse perspiration, impaired breathing, feeble pulse; and death occurs by exhaustion. The symptoms have marked resemblances to cholera states and conditions of chronic catarrh of the bowels. Sickness, vomiting, and purging also occur in cases of arsenical poisoning, but without the intense prostration and profuse sweating characteristic of tartar emetic.

Treatment.—(1) Emetics are not needed, but, if it can be done, washing out the stomach with the syphon-tube will be advantageous.

(2) Tannic and gallic acids form insoluble preparations with tartar emetic; therefore give half a tea-spoonful of either of these in water, and repeat it if it be vomited. Substances containing tannin will also be valuable as substitutes—decoction of oak bark, tincture of cinchona, strong tea infusion, coffee, and these should be given in large quantities till vomiting ceases.

(3) Thereafter give soothing drinks—egg drink, barley or gum water, arrow-root, &c.

(4) To overcome the depression give stimulants, hot, in small quantities repeated, and maintain the patient's warmth by hot bricks, hot drinks, &c.

(5) Nourishing and stimulating injections may be given (p. 873) if the patient seems to be in risk of collapse.

Arsenic.—Poisoning by arsenic, whether by a single large dose or by repeated small doses, whether the poison be given by the mouth or in any other way, exhibits signs of irritation of the stomach and bowels. In the case of large doses the symptoms are acute, and the patient dies within from eighteen to seventy-two hours of the administration. Within half an hour or an hour of the drug being taken, depression comes on; and a severe burning pain is felt at the pit of the stomach, which is increased by pressure on that region. Vomiting next occurs, at first only of the contents of the stomach; but it persists in spite of the stomach being emptied, and bile appears in the vomit owing to the retching; and sometimes the material is streaked with blood. There is also purging, accompanied by pain and violent straining at stool, and blood may appear in the motions. The throat is dry and burning; and thirst is great. The depression and faintness are marked; the skin is cold and clammy; pulse weak and irregular. There may be retention of urine; and a rash may appear on the skin. In cases of chronic poisoning there are loss of appetite, sickness and vomiting, a feeling of tenderness at the pit of the stomach, thirst, dryness of the mouth, redness of the lining membrane of the nostrils, puffy eyelids and reddened eyes, silvery-looking coating on the tongue, headache, irritability of the bowels manifested by frequent slimy motions perhaps mixed with blood, muscular weakness and sometimes even paralysis, beginning with the legs, dry irritable scaly skin, and steady loss of flesh. Death usually occurs by exhaustion.

Death has occurred from 2½ grains of arsenious acid—white arsenic—contained in 2 ounces of fly-water, and from ½ ounce of Fowler's solution of arsenic, which is equal to 2 grains of white arsenic, and death may occur, owing to exhaustion, from a single large dose many days after its administration.

The chronic forms of arsenical poisoning, while they may result from the frequent administration of small quantities, may also be due to the inhalation of dust from fabrics coloured by arsenical dyes, especially green, and to vapour of the poison from other articles. Thus arsenical pigments are to be found in articles of dress, in wall-papers, in artificial flowers, floor-cloths, book-bindings, &c., and it is to be remembered that many fly-papers and rat poisons contain arsenic.

Treatment.—In acute arsenical poisoning—

(1) Ensure thorough emptying of the stomach, and, if possible, washing out of the stomach. This is best accomplished by the stomach-pump or syphon-tube. Failing these, give mustard and water (a table-spoonful of mustard in a tumbler of water), or sulphate of zinc (20 grains) in water, and administer

copious draughts of hot greasy water, salt and water, effectually to clear out the stomach.

(2) Give as an antidote the hydrated peroxide of iron. This is prepared by adding half an ounce of carbonate of soda to an ounce of liquor of the perchloride of iron, or the ordinary tincture of steel. This should be strained through a handkerchief and diluted with hot water. Unlimited quantities may be given. Failing this, repeated doses of one ounce of dialysed iron should be given, or repeated doses of magnesia.

(3) Gummy drinks, barley-water, white of egg and water, linseed tea, should follow the antidote.

(4) Prostration is to be overcome by the free use of stimulants, and by the maintenance of the warmth of the body.

(5) Large doses of castor or olive oil, or a mixture of oil and lime-water, should follow up the above procedure.

In cases of chronic poisoning let the source of poisoning be discovered. Let the wall-paper be examined. Arsenic is not confined to green wall-papers. If the cause cannot be found and removed, let the person seek change of air. The use of quinine and iron tonics and warm baths will promote recovery.

Copper.—Blue-stone, or blue-vitriol, is the sulphate of copper, and verdigris the subacetate of copper. In the case of either of these being accidentally or intentionally swallowed, symptoms of irritant poisoning arise—a metallic taste in the mouth, thirst, sense of constriction and burning in the throat, sickness and vomiting, colicky pains, purging with straining, suppression of urine, hurried breathing, quick feeble pulse, headache, giddiness, stupor, perhaps convulsions. Death may take place within a few hours. The fatal dose of either of the compounds named is from half an ounce upwards.

Chronic forms of copper poisoning may occur from the use of pickles coloured green (p. 600) by the metal, by the use of acid fluids which have been in contact with copper vessels, and it may occur among workers in copper or bronze.

In cases of copper poisoning the vomited material has a greenish or bluish colour which becomes bright blue on adding ammonia.

Treatment in acute cases:—

(1) Empty the stomach by the stomach-tube or an emetic, mustard (tea-spoonful) and water, or ipecacuanha powder (20 grains) in water.

(2) Give white of egg switched in water and milk in large quantities to precipitate the copper.

(3) The after administration of barley-water, arrow-root, gruel, in quantity is to be carried out.

In chronic cases the person should be removed from the source of poisoning.

Lead Poisoning.—The acetate of lead—sugar of lead, the carbonate—white-lead, and Goulard's lotion—solution of the subacetate, have been taken by mistake in poisonous quantity. An ounce of either of the two powders is usually recovered from, and three-quarters of a pint of the lotion have not proved fatal, and cases of acute poisoning are rare. The chief symptoms are dryness of throat, thirst, metallic taste in the mouth, colicky pains chiefly in the neighbourhood of the navel, cramps in the legs, marked constipation, paralysis of the legs, and convulsions. It is the chronic cases that are numerous. They are frequent among workers in lead, plumbers, type-founders, compositors, among workers in lead pigments, painters, artists; and they are often due to contamination of water or other liquids, used for drink, by contact with lead pipes, leaden cisterns, leaden vessels, leaden taps. Cider has been contaminated owing to the glaze in the jars containing lead. Glazers of cards and workers in Brussels lace are said to suffer, and lead poisoning has resulted from the frequent use of hair dyes and cosmetics of which some preparation of lead was an ingredient. Shot used for cleaning bottles has contaminated the drink afterwards kept in the bottles. The contamination of drinking water is considered on p. 642.

The two characteristic symptoms of lead poisoning are colic and "wrist-drop." The colic has been termed "painter's colic," "Devonshire colic," from its association with cider, and "colica Pictonum," from the inhabitants of Poictou, among whom lead poisoning was common owing to the use of lead salts for adulteration purposes. The pain occurs about the centre of the abdomen in spasms like colic, and the abdominal wall is hard and drawn in. The pain is relieved by pressure. The bowels are obstinately costive. The patient also suffers from a feeling of sickness; the tongue is coated, the breath foul; and the patient feels a sweetish astringent taste in the mouth. At the margin of the teeth and gums a blue or violet line is developed. The skin has a dull earthy look, and the countenance is anxious. The "wrist drop" is due to a paralysis of the

muscles which are situated on the back of the forearm and pull the hand backwards, so that when the arm is stretched out the hand drops and cannot be raised. The paralysis may extend to other muscles of the arm, and to the legs and trunk. Rheumatic pains in muscles and joints are common; irritability of temper, sleeplessness, melancholy, and other indications of affections of nerves occur. Blindness owing to wasting of the optic nerves may arise, and disease of the kidneys is sometimes a consequence. Abortion is common in women.

Treatment.—In acute cases—

(1) Empty the stomach by the pump or an emetic of mustard and water, or sulphate of zinc (20 grains), or ipecacuanha powder (20 grains) given in water.

(2) Give, as an antidote, some sulphate—Epsom salts (sulphate of magnesia) or Glauber's salts (sulphate of soda), half an ounce of either in water, or half a tea-spoonful of dilute sulphuric acid in water. Any of these, with a lead compound, forms sulphate of lead, which does not dissolve and is not absorbed into the blood.

(3) Follow up this treatment with bland drinks, barley-water, milk, white of egg in water.

(4) Poultices to the belly will help to relieve the pain.

(5) Five grains of iodide of potassium in water three times daily will help to get rid of any of the drug which has been absorbed into the system.

In cases of chronic lead poisoning—

(1) Remove the person from the contaminating influence.

(2) Give a purgative, the best being sulphate of magnesia, which may be repeated in one-ounce dose for several successive mornings.

(3) Give iodide of potassium in 5-grain doses, dissolved in water, five times daily, for two or three weeks to remove the lead from the system.

(4) Supply nourishing, easily digested food, cod-liver oil and malt, &c.

(5) Sulphur baths, electricity and massage to the paralysed muscles will aid materially in the restoration to health.

(6) Opium or morphia is often required to relieve the colicky pain. It may be given in the form of suppository.

Precautions against further lead poisoning must be taken. Lead-workers who have been affected will require to change their occupation. As preventative measures, lead-workers should be scrupulous in the matter of cleanliness, changing work-clothes when work is over, washing hands, using tooth-brushes, and so on, in order effectually to remove from their person any dust which may contain lead.

Mercury.—Metallic mercury is almost inactive, if not altogether so, so long as it remains in the metallic state. If some of it has been swallowed, and if, in its course through the intestinal canal, any of it undergoes chemical changes into salts of mercury—the oxide, for example—symptoms of poisoning may arise from the absorption of the salt. The chief poisonous preparation is the perchloride of mercury or corrosive sublimate, which is used in medicine as a drug, and in the preparation of lotions and ointments, and is now very largely used as an antiseptic, so that the opportunities for accident are numerous. Symptoms of poisoning may arise from its use in lotions as a dressing or an injection, and symptoms of poisoning are not uncommon from the use of mercurial ointment, which contains metallic mercury, but in a finely divided state. Calomel, the sub-chloride of mercury, may also give rise to poisoning. There are rare instances of the white and red precipitates causing death, and of other preparations of mercury also.

Of corrosive sublimate 2 to 3 grains are believed to be a fatal dose, though recovery from much larger doses has occurred; and of calomel 12 grains have caused death. In acute cases of poisoning death may occur in a few hours or not for several days.

Chronic poisoning from the inhalation of mercurial fumes occurs among workers in mercury—gilders, looking-glass makers, the makers of barometers and thermometers.

Acute poisoning from corrosive sublimate presents symptoms resembling those due to corrosive acids or alkalies (p. 1015). An intense burning sensation is felt in the mouth and throat, which appear white and swollen where the solution has touched. There is a feeling of constriction in the throat, and great pain in the stomach. Vomiting, painful straining, purging often with bloody motions, occur. The skin is cold, pulse feeble, breathing difficult, and other symptoms of collapse are present. Urine is suppressed and convulsions may occur.

In cases of chronic poisoning one of the chief symptoms is salivation, a constant flow of saliva from the mouth. The salivary glands are swollen and tender, so also are the gums and tongue; the breath is very fœtid; ulceration of mouth and throat may occur. Sickness, vomiting, colicky pains, general tremor of the muscles

—mercurial tremor—emaciation and exhaustion, occur. The trembling affects first the upper limbs, but extends to the rest of the body, and occurs only when the person exerts the muscles.

Treatment.—In acute poisoning—

(1) An emetic of mustard and water, or sulphate of zinc (20 grains), or powdered ipecacuanha (20 grains) should be given.

(2) As an antidote give the white of two or more eggs beaten up with water. The albumin forms with the mercury an insoluble albuminate of mercury. Failing white of egg, give flour made into a cream with water, arrow-root and water, barley-water, milk and lime-water. Then empty the stomach again.

(3) Stimulants may be necessary.

In chronic cases remove the person from the source of poisoning. Give iodide of potassium in 5-grain doses thrice daily, and when salivation is marked let some mouth-wash be used—glycerine and tincture of myrrh and borax, for example. Change of air and tonics are valuable; and for the tremors electricity and massage would be useful.

Silver.—Nitrate of silver or lunar caustic as a poison has already been considered among corrosive substances (p. 1020).

Zinc has been a cause of poisoning in the form of chloride of zinc, which is the active material in Sir Wm. Burnett's disinfecting fluid, one ounce of which contains 230 grains. Its symptoms are those of a corrosive poison, like corrosive sublimate.

Treatment.—(1) Warm solutions of carbonate of soda or carbonate of potash or common washing soda. The substance used must be dissolved in a large quantity of water and given freely. Phosphate of soda in plenty of water is also useful. These substances form insoluble salts of zinc.

(2) Milk and eggs in water, decoctions of oak bark, tannic or gallic acids, and strong tea are also to be given.

Sulphate of zinc (white-vitriol or white-copperas), which is given as an emetic in 20-grain doses, has in large doses caused death its symptoms being those of an irritant but not corrosive poison.

POISONING BY ALCOHOL.

Large doses of alcoholic liquors act like narcotic poisons, and may cause death within a few hours. The distinction between insensibility from alcohol and insensibility due to concussion of the brain, apoplexy, and other conditions is not so easily made as is supposed; and so far as immediate aid is concerned, is unnecessary, for the one case demands as careful attention as the other. The effects of drinking it is needless to state here. When a person lies "dead drunk," the face is usually flushed, though it may be pale, the lips are livid, the eyes red, and the pupils are commonly dilated, both equally, though sometimes they are contracted and unequal. The breathing is slow and snoring—stertorous is the technical word. The pulse is slow and laboured, and the skin pale, clammy, and covered with sweat. The temperature of the body is low, and the muscles are all relaxed. A person in this condition lying exposed to the weather, or even under shelter, but without warm coverings, is in grave danger. The loss of the body heat is greatly hastened by alcohol, as explained on page 673, and the exposure to cold may speedily cause death.

The surroundings will usually assist one to arrive at a decision. The proximity of a whisky bottle, the smell of the breath, and so on are useful guides; but they are not to be taken as decisive. A drunk man may have fallen and received a blow sufficient to cause concussion of the brain or fracture of the skull, and his state may be the combined result of alcoholic poisoning and brain injury. He may have been seized with a fit of apoplexy. Caution in coming to a conclusion is, therefore, necessary; and it is best to treat the person as if the condition were grave. Injuries to the head or other parts of the person should be looked for; if squinting were present, or the face were drawn to one side, indicative of paralysis, serious brain injury should be suspected. In opium poisoning the pupils are much contracted, while, as already said, in alcoholic stupor they are usually dilated and fixed.

Treatment.—In many cases it will suffice to bring the patient under cover, to place him in a comfortable position, to restore warmth by the use of friction to the surface of the body, by wrapping in warm blankets, and placing hot bottles at his feet, and then leaving him to sleep off the effects of his excess. In some cases this is not enough. Much spirit may still remain, unabsorbed, in the stomach to maintain and aggravate the condition, when the power of absorption returns. It is, therefore, customary, when the case is serious, to empty and wash out the stomach by means of the stomach-pump, or by means of an emetic, for which purpose a table-spoonful of mustard in a tumbler of warm

water is best for its stimulating properties. Then efforts to rouse the patient should be made. A douche of cold water is wonderfully effective, or flapping the skin with a wet towel; vigorous slapping of the soles of the feet with slippers is often effective when shouting, pulling, and pinching fail. Once roused, the patient should have hot coffee to drink, and if he can be roused enough to take "a good square meal," it has a remarkably sobering effect. Delirium and chronic drunkenness have already been considered on p. 104.

POISONING BY NARCOTICS AND OTHER NERVE POISONS.

Opium, and its active principle **Morphia,** are the chief narcotic poisons, and are responsible for a very large number of deaths annually. The preparations of opium are mentioned on p. 897. Besides laudanum — the tincture of opium—common preparations are nepenthe and chlorodyne, the latter of which contains about 2½ grains of morphia to the ounce, a quantity which has caused death; and it is necessary to remember that paregoric elixir, both the English and Scotch, contain opium as one of their chief ingredients. Children are peculiarly susceptible to the influence of opiates. "It is said on good authority that 15,000 children are killed every year by soothing syrups and other similar preparations" (Murrell). The chief of these are **Dalby's carminative,** which is said to contain about 4 drops of laudanum in each tea-spoonful, and 40 drops have proved fatal to a child; **Godfrey's cordial,** which contains ½ grain opium to each ounce, and against which fifty-six deaths in five years were recorded, the fatal dose for an infant being set down as one tea-spoonful; "Mother's Friend," eight or ten drops of which may be fatal; and **Mrs. Winslow's soothing syrup,** which contains morphia with essence of anise and syrup of balsam of tolu. **Black drop** is a preparation of opium with three or four times the strength of laudanum.

Of crude opium 4 grains have caused death, and the same result has followed from 2 drachms —120 drops—of laudanum. A single grain of morphia has proved fatal. These were cases of adults, but less than ½ grain of opium has killed a child, and 4 drops of laudanum was the cause of death of a child nine months old, while two drops have proved fatal in an infant five days old, and a seven days old child died from the effects of *one drop*. Recovery from large doses, under prompt and vigorous treatment, has often been achieved, and 4 to 6 grains of morphia ought to be recovered from in the case of an adult under good treatment.

Most cases of opium or morphia poisoning prove fatal in from six to twelve hours. A relapse and a fatal termination may, however, occur, after recovery seems to have set in.

The heads of the white poppy, decoctions or infusions of the seeds, leaves, and capsules—poppy-heads, the blossoms and fruit of the red poppy, and syrup of poppies, a sweetened decoction of poppy-heads, have all proved fatal to children, to whom they are not infrequently given as soothing preparations.

The symptoms of opium or morphia poisoning are giddiness, drowsiness, and tendency to sleep, coming on in from half an hour to an hour after the dose has been taken. At the very outset a state of excitement may arise, and a pleasant exhilaration. But if the dose is large this may not appear at all, or very briefly. When the dose is small this may be the main effect, and it is accompanied by wakefulness, and often marked itchiness of the whole skin. Such a state is usually followed by depression, a dull headache, loss of appetite, and a dry mouth. With the larger dose the stage of sleepiness is preceded by headache, a feeling of weight and disinclination for exertion in the limbs, and lessened power of feeling. The face is flushed, and may be dark in colour, and as the poison acts the eyes have a strained feeling, the pupils being much contracted. At first, when insensibility occurs, the person can be roused to answer a question, but immediately drops off to sleep again, and after a time it is difficult or impossible to wake him. As the unconsciousness deepens, the breathing becomes slow and noisy, the pulse faster and softer, the skin pale and livid, bathed at first in warm perspiration, but later cold and clammy. Breathing becomes slower, the intervals between each breath being much prolonged. The pupils are at this time much contracted and motionless. Death arises from failure of breathing, the pulse continuing often at a fairly good rate and moderately strong, even when the breathing seems about to stop.

This condition is distinguished from drunkenness by the pin-point pupils, and the smell of opium is usually marked in the breath.

Treatment.—If the drug has been taken by the mouth (1) it is desirable to remove any from the stomach that may yet be unabsorbed. The stomach-pump is the proper

means for this, since emetics often fail, because of the soothing effect already produced on the stomach. If any emetic be given it should be mustard (table-spoonful) in warm water (a tumblerful), or carbonate of ammonia (30 grains) in water.

(2) Give tincture of belladonna (30 drops) in water, or its active principle atropine, $\frac{1}{40}$ grain. The atropine will act more quickly if given by hypodermic injection, and the dose should be repeated every twenty minutes till signs of recovery show themselves.

(3) Rouse the patient by every possible means, shouting at him, pinching him, pulling his nose, by ammonia to the nostrils, flapping over bare arms and chest with a wet towel, or by a douche of cold water over his head. Keep him walking about as actively as possible.

(4) Give draughts of strong coffee or tea.

(5) Artificial respiration (p. 1011) may be necessary.

The Morphia Habit.—Persons who have found it needful to take opium or morphia for prolonged periods, for the relief of pain, become so habituated to the use of the drug that they are able to take ever-increasing doses, without producing more than pleasurable slumbers and relief of pain. Very large quantities thus come to be used in time, and when the need for the drug has passed away the person cannot give up its use without a most distressing struggle. De Quincey took nine fluid ounces of laudanum, equal to 333 grains of solid opium, daily, and other cases are recorded where as much as 16 ounces were taken daily of laudanum. Those who take such daily supplies are miserable, listless, dull, and unable to work until the usual dose has been taken, shortly after which they become lively, bright, and full of energy and life. But, when the effects have passed off, they are left again in a state of despondency and wretchedness. It requires time and patience to break off such a habit; and not many are found capable of it if left to themselves. A person should be placed in charge of nurses, if the habit is to be rapidly and effectually got rid of, and they must act rigidly on the orders given to them, and must be able to resist the commands and entreaties of the patient for his drug. Complete deprivation of the drug at once is advocated by some, strength being kept up by careful feeding, and stimulants if necessary, other symptoms (headache and sickness) being relieved by cold applications and ice to suck, and sleeplessness by warm baths, a single dose only being given if dangerous collapse threatens. Another method, and the one generally adopted, is to diminish the doses by infinitesimal amounts, so that the diminution is not observed by the patient. Meanwhile every effort is made to restore the shattered health of the patient. One of the most important means is by stimulating nourishing foods, cooked with skill. Tonics containing quinine and nux-vomica are to be given, and the bowels should be kept regular. Stimulants may be required. If so, they are to be used with great care, lest one form of indulgence is got rid of, only to yield to another. For sleep, 30 grains of bromide of sodium in water are given at bed-time. Massage and electricity will be valuable additions to treatment; and active occupation is most desirable. The patient, however, must be so constantly watched and supervised that it is impossible for him to obtain a surreptitious dose.

Chloral Hydrate poisoning resembles that of opium in many particulars. Deep sleep comes on quickly, with great muscular relaxation. The face is livid and bloated; breathing is much interfered with, slow and noisy; pulse is weak and quick. The temperature of the body falls to a great degree. The pupils are contracted while the patient is asleep, but, if he is roused, they dilate. Death occurs by failure of the breathing or the heart. Such a result has occurred from a dose of 30 grains, though recovery has taken place after 460 grains had been swallowed.

The treatment is the same as that for opium. The stomach should be emptied by the stomach-pump or an emetic. The heat of the body must be quickly restored by friction, hot bottles, hot blankets; and the patient must be roused and kept awake. Hot coffee is given to drink. The only substance approaching to that of an antidote to chloral hydrate is strychnine, of which 5 to 8 drops might be given by the mouth, or 15 drops of the tincture of nux-vomica. Artificial respiration may be necessary for hours to prevent failure of breathing.

Chlorodyne Poisoning is due to the opium contained in the drug, and the treatment is that of opium poisoning.

Prussic Acid or **Hydrocyanic Acid.**—This in its pure and undiluted state is one of the most deadly and rapid of poisons. A single drop will cause death. The vapour of the poison is also destructive to life. The undiluted acid is not obtainable, but two preparations are in use, the dilute acid of the British Pharma

copeia, which contains 2 per cent of the undiluted acid, and the dilute acid of Scheele, which contains 4 per cent. Twenty-five drops of the latter solution would, therefore, be the smallest fatal dose. Recovery, however, has taken place, under treatment, from $2\frac{1}{2}$ times this quantity. The drug acts with great rapidity, in its concentrated form practically instantaneously. Large doses of the Scheele's acid—3 or 4 drachms—would begin to act within 10 or 15 seconds, and 1 drachm—60 drops—within a minute. The symptoms, in cases where a fatal dose has been taken, are rarely delayed beyond 1 or 2 minutes, and death occurs within 5 or 10 minutes.

Symptoms.—When the dose is not so great as to cause death instantaneously, the symptoms are giddiness, mental confusion, difficult breathing, and slow irregular pulse. Insensibility then comes on, the pupils are widely dilated, the eyes open, fixed and glistening. Breathing is gasping, the effort to breathe out being prolonged. The face is livid, the skin cold and clammy, and violent convulsions may occur. There is often vomiting and involuntary emptying of the bowels and bladder. The jaws are firmly closed and the hands clenched.

Noyau (p. 668) contains prussic acid; **Cherry Laurel Water** and **Oil** owe their odour and active principle to prussic acid, of which the former contains $\frac{1}{4}$ per cent of the undiluted acid, and the latter about 3 per cent. The kernels of peaches, apricots, almonds, &c., contain the acid, and deaths have occurred from eating them (p. 580).

Cyanide of Potassium, a compound of prussic acid and potash, is much used in photography and electro-plating, and has proved fatal with symptoms of prussic acid poisoning.

Treatment must be very quick and energetic.

(1) Use the stomach-pump or secure vomiting by mustard (1 table-spoonful) in warm water, sulphate of zinc (20 grains), or ipecacuanha wine (two table-spoonfuls).

(2) Give stimulants instantly and freely, ammonia (15 drops) in water, brandy or whisky in water, and let ammonia be inhaled from a handkerchief, or use smelling-salts.

(3) Dash cold and hot water alternately over the head and chest of the person to stimulate the breathing.

(4) Resort to artificial respiration and maintain it steadily.

(5) Atropine has been urged as an antidote, $\frac{1}{50}$ grain injected under the skin to be preferred, or 15 drops tincture of belladonna by the mouth.

Alongside of prussic acid must go the **Essential Oil of Bitter Almonds**, which is from five to eight times as strong as the British Pharmacopeia dilute acid, and 17 drops of which have proved fatal, and the **Spirits of Almonds**, used for almond flavouring, which is about the same strength as the dilute pharmacopeia acid.

Aconite (*Aconitum Napellus*, Plate XIII., Wolf's-bane or Blue Rocket or Monkshood).—All parts of the plant are poisonous. The root has been taken in mistake for horse-radish; eating the fresh leaves has been the cause of children's death; for the plant grows wild everywhere. Medicinal preparations (see p. 834) have occasioned many deaths. The active agent is an alkaloid — aconitia. It is used in medicine chiefly in the preparation of an ointment for neuralgia, and it is the chief constituent in **Neuraline**, an application for neuralgia. Sixty drops of the tincture have proved fatal, though recovery has occurred after larger doses.

The **symptoms** are tingling of mouth, lips, and tongue, and a feeling of warmth at the pit of the stomach. Tingling extends to the whole body, followed by numbness and diminished sensibility of the skin. A feeling of faintness comes on; there is sickness and often vomiting. The heart's beats become weak and lessened in number; the breathing is shallow and infrequent; and deafness and dimness of sight arise. Convulsions may occur; death is due to prostration; but there is no disturbance of the intelligence, and the pupils are dilated.

Treatment.—(1) Use stomach-pump or emetic.

(2) To antagonize the poison give 4 drops solution of atropine by the mouth, or 20 drops tincture of belladonna. If the pulse improves give a second dose in half an hour, or give 20 drops tincture of digitalis, followed in two hours by a similar dose, if the pulse has improved with the first.

(3) Stimulants to be given freely, and the warmth of the body to be maintained.

The person should be kept strictly lying flat.

Atropia and Belladonna Poisoning.—Belladonna, Deadly Nightshade, or Dwale grows wild, and produces berries of a dark shiny colour, about the size of a cherry, marked with a deep central furrow (Plate X.). These berries have been eaten by children, and have even been cooked in a pie. The effects produced by any of the medicinal preparations, or

by using parts of the plant, are due to the active principle atropia. Recovery has taken place in the case of a child who had eaten fifty berries; death has been caused by a drachm of the liniment of belladonna, though recovery has taken place after much larger doses. The symptoms are heat and dryness of the throat and mouth, great thirst, absence of saliva, and difficulty in swallowing. The face is flushed a bright scarlet, the eyes are bright and sparkling, and the pupils widely dilated and insensible to light, while vision is blurred. The patient is excited and delirious; there is loss of muscular power. The skin is dry, and there is sometimes a rash like that of scarlet fever; and there is inability to pass water, though a frequent desire to do so. Drowsiness comes on; the breathing is hurried, and the pulse feeble. Convulsions occur, stupor, and death.

Treatment.—(1) Empty the stomach by stomach-pump, or by emetic of mustard, sulphate of zinc, or ipecacuanha.

(2) Administer as an antidote extract of physostigmine, the Calabar bean, of which $\frac{1}{4}$ grain in pill may be given every half-hour for several doses.

(3) Stimulants, whisky, brandy, hot coffee, are to be given freely, and the patient is to be kept warm.

(4) Artificial respiration may be necessary.

The prospects of recovery are always hopeful.

Calabar Bean (see p. 902) in poisonous doses causes loss of power in the legs, prostration, contracted pupils, and death from failure of breathing.

Treatment.—(1) Empty the stomach by the pump or an emetic.

(2) Give as an antidote, 15 drops of tincture of belladonna in water, and repeat the dose every quarter of an hour for four doses, or until the pulse is improved and the pupils dilated.

(3) Give stimulants freely; and maintain breathing if necessary by artificial respiration (p. 1011).

Cannabis Indica (Indian Hemp) produces a species of intoxication like opium. Later a feeling of weight in the legs and intense depression come on, and subsequently sleep and stupor. Treat as for opium poisoning (p. 1025).

Poisoning by Henbane or Hyoscyamus is attended by symptoms similar to those which follow poisoning by belladonna, to which the reader should refer (p. 1027). The root of the plant has been eaten in mistake for parsneps.

Poisoning by Datura Stramonium (Thorn-apple—Devil'sApple—Jamestown Weed).—The leaves of this plant (see Plate XII.) have been mistaken for senna leaves, and a deadly infusion made; children have died of eating the seeds.

The symptoms resemble those of belladonna poisoning, flushed face, fixed dilated pupil, indistinct vision, delirium, convulsions, paralysis, and death. One hundred seeds killed a two-year-old child. Treatment is the same as for belladonna poisoning.

Nux-vomica and Strychnine.—The powdered nux-vomica seeds and their active principle strychnine are used in the manufacture of vermin killers, such as Butler's, Battle's and Gibson's, and thus accidents arise. Thirty grains of powdered nux-vomica have proved fatal, so also have three grains of extract, while of strychnine a half grain to two grains is the fatal dose for an adult, but a child between two and three years of age was killed by a sixteenth part of a grain. In fatal cases death generally occurs within two hours. In one case death occurred in twenty minutes after the poison was taken.

Symptoms.—All preparations of nux-vomica and strychnine have an intensely and persistently bitter taste, and if the drug has been taken by accident, this bitterness will certainly strike the person. The symptoms begin within fifteen or twenty minutes of taking the drug. There is a sense of impending suffocation, restlessness and excitement, a preternatural acuteness of sight, hearing, and taste, twitchings or jerkings of the head and whole body, and then, in an instant, the whole body is seized with a violent convulsion. Every muscle is fixed and rigid, head thrown back, chest fixed, corners of mouth drawn down, and by the rigidity and contraction of muscles the whole body becomes arched backwards, in which case it rests on the back of the head and soles of the feet, like a bow, a position called **opisthotonus**. At this time, owing to the rigidity of the chest, breathing is arrested, and the face becomes bloated and dark; the eyes are prominent and the pupils dilated, but consciousness is not lost. In half a minute or a little more the muscles relax completely, and the patient lies exhausted and bathed in perspiration, the breathing becoming regular, and the lividity passing off. But soon another spasm, perhaps more violent than the first, seizes the person, following the same course, to be succeeded also by another, till death occurs from exhaustion or suffocation. The slightest thing will determine a renewal of the spasm, even a whiff of cold air upon the skin.

Treatment.—(1) Give an emetic of a table-spoonful of mustard in a tumbler of water, or 30 grains of sulphate of zinc in water, or 20 grains ipecacuanha; the stomach-pump is not available unless immediately after the poison has been taken, because of the risk of determining a convulsion.

(2) Give quantities of animal charcoal in water, or 30 grains of tannic acid in water, and a second emetic to empty the stomach.

(3) To lessen the spasms give 30 grains of chloral hydrate along with 60 grains of bromide of potassium, and every fifteen or twenty minutes give additional doses of 10 grains of chloral hydrate with 60 grains bromide of potassium so long as the tendency to spasm exists.

(4) Chloroform or ether inhalation is useful, if one is at hand used to their administration.

(5) It is necessary to keep the person warm and absolutely quiet, every noise of shutting door or sudden sound being liable to determine a convulsion.

(6) Artificial respiration may be needful.

Paraffin-oil (Petroleum, Rock-oil, Kerosene, Mineral Oil). — If such mineral oil has been swallowed, the smell of the breath and vomited matters will indicate it. Great prostration is produced, pain in throat and stomach, thirst, restlessness, and stupor.

Treatment.—(1) Use a stomach-pump, or an emetic of sulphate of zinc or ipecacuanha powder (20 grains) in water.

(2) Give stimulants freely, and keep the patient warm.

Poisoning by Vegetable and Animal Irritants.

Many vegetable substances, used in medicine, when given in excessive doses produce symptoms of poisoning by intense irritation of the stomach and bowels, vomiting, purging, pain in the abdomen, great prostration, weak pulse, moist skin, and collapse.

Such substances are:—

- Aloes,
- Castor-oil Seeds,
- Croton-oil,
- Colocynth,
- Elder Leaves and Flowers,
- Gamboge,
- Hiera-picra, a compound of aloes with canella bark,
- Podophyllum (May-apple or Mandrake).

Treatment should be directed

(1) To remove the substance by emetic of mustard (table-spoonful) in water,

(2) to quiet the stomach and bowels by warm bland drinks, white of egg and water, milk (iced), gummy water, barley-water, and by the use of warm poultices to the abdomen,

(3) to overcome the depression by brandy or whisky or aromatic spirits of ammonia, administered in tea-spoonful doses, frequently, as seems necessary.

(4) Camphor may be given, 10 drops of spirit in milk, every ten minutes, for three or four doses.

(5) If necessary, to relieve pain and stop purging, give 5 to 20 drops of laudanum in water, repeated in an hour, if needful.

Arum maculatum (Lords and Ladies, Cows and Calves, the Parson in the Pulpit, Wake-robin, Cuckoo-pint).—This is a poisonous plant, common in moist hedgerows and shady woods in England. Its bright-coloured fruit (Plate XII.) is a temptation to children. It produces severe irritation of mouth, stomach and bowels, causing swelling of the tongue, vomiting and purging. The pupils are dilated; convulsions and insensibility precede death.

Treatment.—(1) Give an emetic—20 grains sulphate of zinc or 20 grains ipecacuanha powder.

(2) Follow this with a full dose of castor-oil.

(3) Give a large cup of hot strong coffee, and stimulants as well.

(4) Keep the patient warm and relieve the bowel pain by warm poultices.

Camphor (p. 850).—The chief symptoms of camphor poisoning are nervous in character. A species of intoxication is produced, with giddiness, faintness, noises in the ears, delirium, convulsions, disturbances of vision, prostration. The pulse is quick and feeble, and the breathing difficult; and there may be pain and difficulty in making water. A piece the size of a nut has killed a child; but recovery has taken place from even nearly ½ ounce.

Treatment.—(1) Use the stomach-pump or an emetic.

(2) Give stimulants freely, preferably by injection into the bowel, as spirits given by the mouth would dissolve solid camphor in the stomach.

(3) Dash hot and cold water alternately over the head and chest.

(4) Keep the patient warm.

Cantharides (Spanish-fly) cause great irritation of mouth, throat, stomach, and bowels. There is vomiting and purging, blood being vomited and passed. The urine is bloody; there is strangury, fever, swelling of the salivary

glands, loss of sensibility, and convulsions. Death has taken place from 24 grains, but recovery after an ounce.

Treatment.—(1) Empty the stomach by a pump, or give an emetic.

(2) Follow with soothing drinks, gummy or barley water, white of egg in water, iced milk, &c.

(3) Apply hot poultices to the belly, and give 30 drops of laudanum to relieve pain.

Cocculus Indicus is the berry of *Anamirta Cocculus*, a climbing East Indian shrub. The seed, which contains the poisonous ingredient, an active principle called **picrotoxine**, is inclosed in a dark brown husk, which contains no poison. If the whole berry is swallowed, less risk of poisoning occurs from the hard husk preventing digestion of the kernel. The seeds are fraudulently added to beer to increase its intoxicating property, and the powder is used in medicine as an ointment for vermin and skin diseases.

Symptoms are sickness, vomiting, muscular weakness, intoxication and stupor, sometimes convulsions.

Treatment.—(1) Use stomach-pump or an emetic.

(2) Give charcoal in water and again excite vomiting.

(3) Give 20 grains chloral hydrate in water, to be followed if necessary in fifteen minutes by a second dose of 10 grains. Bromide of potassium in 60-grain doses may also be given.

Digitalis Poisoning is not common, though accidents arise from the use of the medicinal preparations. The symptoms are sickness with vomiting of greenish material, purging with pain in the abdomen, small irregular slow pulse, and faintness if the patient attempts to sit up. The symptoms increase in severity with larger doses, pupils being dilated and fixed, the skin pale and covered with a cold sweat, urine is suppressed, and stupor precedes death.

Treatment.—(1) Use stomach-pump or emetic of mustard, zinc sulphate, or ipecacuanha.

(2) Give as an antidote 6 drops of tincture of aconite, and repeat it in half an hour if the heart's action has improved.

(3) Give stimulants freely, whisky, brandy, aromatic spirit of ammonia, ether, hot coffee, and if they are not retained on the stomach inject them into the bowel.

(4) The person must maintain the lying position for some time after the danger is over. Any attempt to sit up would be attended by danger of fainting.

Hellebore.—There are two varieties of hellebore, the **White** or *Veratrum album*, and the **Green** or *Veratrum viride*, or **American Hellebore**, called also **Swamp Hellebore** and **Indian Poke**. All contain an active principle—**veratria**—to which the poisonous action is due. From **Sabadilla** or **Cevadilla**, the dried fruit of a Mexican plant, *Asagræa officinalis*, this veratria is usually obtained.

The symptoms are those of irritation of the digestive canal, parched mouth, burning sensation in gullet, thirst, retching, vomiting, painful purging. There are also symptoms of nervous origin, headache, faintness, palpitation, a feeling of anxiety, pupils generally dilated, weak slow pulse, laboured breathing, and perhaps convulsions.

Treatment.—(1) Use stomach-pump or emetic.

(2) Give stimulants freely, alcoholic stimulants and hot strong coffee.

(3) Maintain the warmth of the person's body and keep him lying quite flat.

Hemlock Poisoning.—Several plants may be included in this paragraph. There is the Greater, Common or Spotted Hemlock, the Water Hemlock (*Cicuta virosa*), Fool's Parsley (*Æthusa Cynapium*, Plate XI.), Hemlock Water Dropwort (*Œnanthe crocata*). Their leaves have been eaten in mistake for parsley, and the roots of the last-named for parsnep. A whistle made of the twigs of the common hemlock has been the cause of death.

The symptoms begin with excessive weakness of the legs, which causes a staggering gait; and the weakness extends until it involves the whole body. There are sickness and a burning pain in mouth and throat. The upper eyelids lose their power and droop over the eyeballs, so that, on acount of the muscular weakness and this combined, the patient lies quiet with eyes closed. The pupils are fixed and dilated. The muscular weakness, going on to paralysis, gradually extends upwards till the heart and breathing become affected, and there is inability to swallow. Death arises from failure of breathing.

Treatment.—(1) Use the stomach-pump, or an emetic of 20 grains sulphate of zinc, or the same quantity of ipecacuanha powder.

(2) Give large quantities of strong tea or coffee, decoctions of oak bark, tannic or gallic acid in 10-grain doses, to precipitate the active principle of the drug in the stomach and prevent its absorption.

(3) Give stimulants of brandy, ether, ammonia; and keep the person warm by friction, hot blankets, &c.

(4) Artificial respiration should be resorted to to maintain the breathing, and 10 drops of tincture of belladonna may be given to stimulate the breathing.

Laburnum bark, leaves, pods, flowers, and seeds are all poisonous, owing to the presence of an active principle **cytisine**. Numerous cases of poisoning in children from eating the pods and seeds have occurred.

Symptoms are those of stomach and bowel irritation, accompanied by nervous symptoms. They are sickness, vomiting, and purging, pain in the belly, straining at stool, pallor and exhaustion, great restlessness, slow feeble pulse, drowsiness, insensibility, and muscular twitchings.

Treatment.—(1) Use stomach-pump, or mustard and water emetic, or ipecacuanha wine, an ounce in water.

(2) Give hot coffee and stimulants of whisky, brandy, or ammonia.

(3) Use a douche of hot and then cold water to the head and chest.

Lobelia Inflata (Indian Tobacco).—Many deaths are attributed to the administration of the leaves of this plant by so-called "medical herbalists." Sixty grains of the powdered leaves are likely to prove fatal. It acts as an irritant upon the stomach and bowels, producing sickness and vomiting, pain and purging, and great depression. Later, it produces nervous symptoms, muscular tremors, headache, giddiness, insensibility, and convulsions.

Treatment.—(1) If vomiting has occurred, an emetic may be unnecessary; if it has not occurred, give mustard and water, or zinc sulphate (20 grains), or ipecacuanha.

(2) Give strong tea, or tannic or gallic acid in a 30-grain dose in water.

(3) Stimulants are to be freely given, and warmth to be maintained, the person being kept lying.

(4) Give 20 drops tincture of nux-vomica as a nerve stimulant.

Meadow Saffron or **Colchicum** (Autumn Crocus) acts as an irritant to the intestinal canal, acting also upon the nervous system. Its irritant properties are displayed by irritation of the throat, thirst, burning pain in the stomach, persistent vomiting and purging. Accompanying these symptoms are intense prostration, weak fast pulse, much perspiration, and muscular twitchings. One ounce of colchicum wine has thus caused death.

Treatment.—(1) Stomach-pump or emetic.

(2) Strong tea, decoction of oak bark, or 20-grain doses of tannic or gallic acid.

(3) Free use of stimulants and drinks soothing to the irritated membrane of the stomach, white of egg drink, gum-water, barley-water, &c.

Nightshade, the **Woody Nightshade** (*Bitter Sweet*, or *Solanum Dulcamara*) with purple flowers and red berries, **Black** or **Garden Nightshade** (*Solanum Nigrum*) with white flowers and black berries, and the **Potato Apple** (*Solanum Tuberosum*), are sometimes partaken of by children because of the attractive appearance of the fruit, and cause poisoning. The symptoms are those of irritation of stomach and bowels described above, along with symptoms of nerve disturbance, stupor, convulsions, delirium, dilated pupils. Treatment consists of an emetic as ordered for lobelia (see above), a purgative of castor-oil to expel any material in the bowel, and stimulants.

Privet Berries (*Ligustrum vulgare*) have also been responsible for deaths in children.

Symptoms and treatment are similar to that adopted in cases of poisoning from yew berries.

Pulsatilla (p. 893) and **Poke Berries** (*Phytolacca decandra*) belong to the same type of poisonous plants as privet berries, so far as symptoms and treatment are concerned.

Tobacco (*Nicotiana Tabacum*).—The poisonous active principle of tobacco is **nicotine**, which when pure is a very deadly poison. Cases of poisoning have occurred from using an infusion or decoction of tobacco for worms or to procure abortion. The symptoms are sickness, vomiting, great depression, and faintness, dimness of sight, weak pulse, cold clammy skin, convulsions and stupor.

Treatment.—(1) Use stomach-pump or emetic of large draughts of water, mustard (table-spoonful) in water, sulphate of zinc or ipecacuanha powder (20 grains) in water.

(2) Give strong tea, or 20 grains tannic or gallic acid.

(3) Use stimulants freely, brandy, aromatic spirit of ammonia, &c.

(4) Keep the patient warm, lying flat in bed.

(5) Give 20 drops tincture of nux-vomica in water.

Turpentine, taken by mistake or given for worms, may produce poisonous symptoms re-

sembling those of opium, namely intoxication, then insensibility with contracted pupils, weak pulse, noisy breathing, stupor and convulsions. The treatment would be draughts of mustard and water to induce vomiting, milk, egg-water, barley-water, gummy water, and one ounce of Epsom salts in water to act as a purge.

Virginia Creeper (*American Ivy, Ampelopsis quinquefolia*).—The leaves of this plant, chewed by children, have occasioned poisoning with symptoms like those produced by yew berries. Treatment is the same.

Yew Berries and Leaves (*Taxus Baccata*) are also poisonous, and deaths of children have resulted from their being eaten. A tea of the leaves is sometimes used to restore monthly illness.

Symptoms are perhaps vomiting and purging, paleness of face, coldness of extremities, small pulse, dilated pupils, insensibility, and convulsions.

Treatment.—(1) Emetic of a table-spoonful of mustard and water, or 20 grains of either sulphate of zinc or ipecacuanha powder in water, to be followed by

(2) Stimulants of brandy, whisky, or aromatic spirit of ammonia.

(3) Maintain warmth by friction, hot bottles, &c.

Poisonous Clothing, Wall-papers, Hair Dyes and Cosmetics.

Poisonous Clothing is considered on p. 732.

Poisonous Wall-papers.—See Arsenic, pp. 823.

Poisonous Hair Dyes and Cosmetics.—Hair dyes and enamelling liquids for the skin frequently contain lead, and are apt to occasion symptoms of chronic lead poisoning (p. 1022). Lotions for the complexion are sometimes poisonous because of the presence of corrosive sublimate (p. 1023).

Poisonous Food.—See Unwholesome Food (p. 597), and see pp. 646, 653 for impurities in waters. Poisonous mushrooms are considered on p. 583.

Section VII.—AMBULANCE AND STRETCHER DRILL.

Ambulance:
- *Army Ambulance Work;*
- *Ambulance for First Aid in Civil Life.*

Stretchers and Stretcher Squad Drill:
- *Formation of Company for Stretcher Drill;*
- *Formation of Stretcher Squads;*
- *Exercising Squads with Stretchers;*
- *Equipment of a Stretcher Squad.*

Ambulance.

Army Ambulance Work.—In the English army ambulance system each division of an army corps has connected with it a Divisional Ambulance Company. This consists of two bearer companies, each of which is composed of 1 surgeon-major in command, 2 surgeon-captains or surgeon-lieutenants, 1 sergeant-major, 6 staff sergeants and sergeants, 6 corporals, 47 privates, and 1 bugler, as well as the officer and men of the Army Service Corps attached for transport duties. As every army corps numbers 3 divisions, each of which, as we have said, has 2 bearer companies, and as the army corps has besides a cavalry brigade, which has 1 bearer company (a half divisional ambulance company) attached to it, and a body called the Corps Troops, of reserve artillery and engineers, which has also 1 bearer company, each army corps has thus 8 bearer companies (or 4 divisional ambulance companies). The men of a bearer company belong to the Medical Staff Corps, and have no relation to the regiments, battalions, or brigades composing a division. They are an integral part of the Medical Department of the army, which is a completely separate organization. The bearer company is subject to its surgeon-major in command, and the two bearer companies of a division, forming the divisional ambulance company, are under the command of the principal medical officer of the division, while the four divisional ambulance companies of the army corps are medically administered by a surgeon-general on the staff of the general in command of the army corps. Each bearer company has a surgery wagon, fitted with baskets containing instruments and medical and surgical appliances, cooking utensils and medical comforts for the wounded, and carries an operating table, and surgical dressing tent, for fitting up at the dressing station; it has also

A STRETCHER SQUAD MARCHING WITH LOADED STRETCHER.

This shows a stretcher squad marching with a loaded stretcher, as described on p. 1041. The man carrying the foot end of the stretcher is No. 1 Bearer, the man at the head end is No. 3. No. 4 is on the right side, and No. 2 on the left. The extra man, with the three stripes on his arm, is the Sergeant in charge.

Plate XVIIIa.

A STRETCHER SQUAD MARCHING WITH LOADED STRETCHER.

water carts and 10 ambulance transport wagons, as well as pack transport including cacolets and litters, field panniers borne by mules, &c. Further, each bearer company is disposed into 2 sections, each composed of 4 stretcher squads, each stretcher squad having a stretcher and 4 bearers, 2 to carry the stretcher, and 2 for relief, the latter two carrying surgical haversack and water-bottles. Thus in every bearer company there are 8 stretcher squads with 8 stretchers and 32 bearers under non-commissioned officers, the remaining members of the company being intended for duty at collecting and dressing stations.

When a division is on the eve of going into action, the 2 bearer companies of its divisional ambulance company form a dressing station, directly in the rear of the fighting line, but if possible out of fire. Here the operating tent is pitched and arrangements made for examining and classifying wounded and doing necessary operations and dressing, and administering food, &c., the officer-commanding and one other medical officer being in attendance. From the dressing station the ambulance transport wagons are sent forward to a position as near the fighting line as possible, where a collecting station is formed. Here the wagons are drawn up, and from this station the stretcher squads are sent forward, under one of the medical officers, on to the battle-field itself. A stretcher squad is ready to do any absolutely necessary dressing, to stop bleeding, &c., to give water or stimulant, and, as quickly as may be, places the wounded soldier on a stretcher, or otherwise assists him to the collecting station. At the collecting station the stretcher squads wait only long enough to transfer the wounded to the ambulance wagon, and return to the battle-field, never going in rear of the collecting station. The wagons then transport the wounded to the dressing station and again return to the collecting station. Such are the arrangements for giving immediate succour to the wounded.

Besides these arrangements there are others. Further in rear of the division, out of reach of the action, are the field-hospitals of the division, to which the wounded are taken from the dressing stations. Of these there are fourteen to each army corps, each fitted to receive 100 wounded. Here the slightly wounded may remain till they are able to go to the front and rejoin their regiment. These field hospitals move with the army, two or so miles in its rear, but still behind them, and planted in the line of communications between the army and its base are stationary hospitals, each capable of treating 200 wounded, while at the base itself there are general hospitals, capable of accommodating 500 each. Finally, between the base hospital and the permanent military hospitals at home are the hospital ships. All these arrangements, it will be noted, are under the control of the Medical Department of the army, the head of which is the Director-general of the Medical Staff; and, as already said, the members of the Medical Staff Corps have no connection with the regiments or brigades. But each regiment or battery or brigade has its medical officer, who goes with his regiment, and has a certain amount of drugs and dressing materials with him, sufficient to meet ordinary cases not requiring prolonged treatment. He has, to assist him, trained bearers, with stretchers and surgical haversacks, obtained from the regiment to the number of two soldiers per company. They form the Regimental Ambulance Bearers, have nothing to do with the organization of the Medical Staff Corps, and follow the regiment wherever it goes. In action they move about the battle-field, always in touch with their own corps or regiment, giving succour, and carrying wounded to the rear, where they hand them over to the men of the Medical Staff Corps.

In the volunteer army, until quite recently, there was almost no ambulance organization. Each regiment had one or more medical officers, but there was no bearer company, not even a stretcher squad. Recently this had been remedied to this extent, that most regiments have now an ambulance company of one or more stretcher squads with trained bearers. Behind the regiments, the deficiency was still greater. Now a Volunteer Medical Staff Corps is being raised in England and Scotland, but a regular organization of a bearer company under a principal medical officer for each regimental district is not yet within reach of realization.

Ambulance for First Aid in Civil Life. —In civil life accidents are frequent—on the street, on the railway, in the workshop, in the mine, at the dock; and much suffering and even loss of life are occasioned by the ignorance of those about the injured man, their inability to recognize what aid may be temporarily useful, and their awkwardness even in transporting him to some place where help may be obtained. In 1878 the St. John's Ambulance Association was founded in England to meet these conditions. Its objects were, by means of classes, open at little or no fee to the public, to teach the people how to render intelligently first aid to

injured persons pending the arrival of skilled medical assistance, and to place stretchers, ambulance wagons, and other appliances in suitable places for the ready and safe transport of injured persons to hospital. In 1882 the St. Andrew's Ambulance Association was founded in Scotland with similar objects. The centre of the former association is in London, of the latter in Glasgow, but they have branches all over the kingdom, and everywhere local committees can be got up and arrangements made for lectures on "First Aid". As a result of the work of these organizations very many persons of both sexes have received a training in "First Aid", so that were a person seriously injured in a busy thoroughfare, it is almost certain someone would be found in the neighbourhood who knew at any rate how to prevent further injury being done by kindly but uninstructed Samaritans. Many of the police of the larger towns have passed through ambulance classes, and in large public works, collieries, and so on, workmen have been trained to form an ambulance corps, while similar bodies exist in connection with the leading railways, composed of railway servants. In many industrial centres wagons are now placed, so that seriously injured persons can be safely carried to hospital. In America, in New York, Boston, and Chicago, civil ambulance arrangements are very complete. In New York the municipal district hospitals have regular wagons and a staff of surgeons and attendants always ready. The hospitals are in telephonic communication with the police stations and the leading thoroughfares, and within a few minutes of an accident a completely equipped wagon with a trained attendant can be on the spot.

The St. John's Ambulance Association, it may be mentioned, was formed in connection with the Knights of the Order of St. John of Jerusalem, one of the knightly orders of crusader days, founded to relieve the sufferings of the pilgrims to the Holy Land and crusaders. Then the Red Cross Societies, which sprang from the conference at Geneva, on 9th February, 1863, called to consider the subject of the treatment of wounded in war, exist in every European country. They are civil societies which send help to the field of war wherever it be, and whose flag with the red cross is recognized as protecting from molestation by either army.

Stretchers are contrivances on which wounded and helpless persons can be transported easily and without risk of injury from one place to another. As they are now familiar not only to the members of an army ambulance corps, but also, through the agency of ambulance classes, to a steadily increasing number of civilians, it will be well to note their construction. One of the earlier forms of stretcher was that devised by Baron Percy for the French army. It consisted of two parts, interchangeable. Each bearer carried a part, and thus any two bearers could in two or three minutes put together a stretcher and carry a wounded man from the field. Each part consisted of a pole, 8 feet long. At one end was fitted a lance head, of such a shape and so fixed that it could be detached and sheathed in a scabbard at the bearer's side. When it was fixed on the pole it provided the bearer with a weapon of a lance description, and when detached it could still be employed for attack or defence. The other end of the pole was provided with a ferule. Another portion of each bearer's equipment was a piece of canvas of the proper length for the stretcher, but only half the breadth. Along one side was a broad hem, into which the pole could be passed, along the other side of the canvas was a row of eyelet holes. When each bearer had taken off the lance-shaped point of his pole, and passed the pole along the hem of his piece of canvas, he had half a stretcher, and these two halves were laced together by a cord fastened to the sacking. The stretcher was still, however, incomplete, for if it were laid down a person lying on it would have nothing but the sacking between him and the ground. Besides, the weight of a person's body would cause the two poles to come together, unless some rigid material extended between the two poles to keep them apart. Accordingly, each bearer carried over his knapsack a broad piece of wood long enough to extend from one pole to another. Near each end of this cross-piece was a round hole through which one of the poles was passed, and each end was prolonged downwards a sufficient length to act as a foot, so that when the stretcher had been fitted with one of these at each end, the two poles were kept fully apart, the canvas was kept stretched, and when the stretcher was laid down the feet kept the canvas off the ground, and the wounded man was thus protected from wet, damp, or cold ground. Under cover, in the absence of other appliance, the stretcher could act as a hospital bed.

The present regulation stretcher of the English army is known as "Surgeon-major Faris's Stretcher", and is thus described by Surgeon-major Evatt: "It is most solidly built, and consists of two side poles of ash, brown canvas bottom, a pillow, two self-locking traverses,

which lock under the stretcher and keep it open. There are four wheels of lignum vitæ, on which the stretcher rolls into the ambulance wagon, and which act as legs when used as a camp bedstead, a use to which all army stretchers are liable. It weighs 32 pounds, and costs at the Royal Arsenal, Woolwich, about £3. To aid the bearers it has two leather slings, one at either end, which the bearers put over their neck like a milkman's yoke, and so relieve their arms of part of the weight." A strap fixed transversely near one end of each sling keeps both poles together when the stretcher is folded up.

Besides the poles on which the canvas is stretched, the requirements of a stretcher, which permit of many varieties of form, are the traverses, the cross-pieces, that is, which keep the poles apart when the stretchers are prepared for use, and the feet. In the English pattern the traverse is in two halves, one being fixed on each hole, and they are hinged at the centre, the end of one half overlapping that of the other half and hooking on to it when the traverse is straightened. The traverses are fixed near the ends of the stretcher, so that the bearer's hand passed under the end of the canvas readily grasps the traverse, and straightens it, thus separating the poles to the utmost, and fixing them. The feet also permit of many varieties of form, some as in the Faris pattern having small wheels in a fixed position, others having feet which fold up when the traverse is folded, and extended when the traverse is straightened. There is yet needed, however, a stretcher for both army work and for accidents in civil life, which besides being strong enough to fulfil all the requirements of carriage, will also be so light that one man can run with it, so arranged and made of such material that it can be folded up so as to occupy small space, so simple in construction that no mechanical knowledge is required to understand its parts, that it is not easily broken and not apt to get out of order.

Various modifications have recently been devised for use in mines and pits, where accidents are so numerous, which permit an injured man to be raised up the shaft in a comfortable position and secure from slipping.

Surgeon-major Evatt recommends, and ambulance associations all over the country are endeavouring slowly but steadily to realize it, "that stretchers should be kept in every street in our great cities, in a stretcher locker [painted red] of which the police and certain residents should have keys. Every railway-station should also have one, also every guard's van in all passenger trains. No public school, factory, institution, or asylum should be without such aid in carrying injured people. Probably many chemists would be glad to keep such stretchers in their pharmacies, and exhibit a notice to that effect in their windows, if any philanthropic society would provide the article."

Stretcher Drill.—Ambulance classes for giving to civilians training in rendering first aid to injured persons are now numerous all over the country. Part of the instruction they invariably receive is in the use of stretchers, and a modification of the stretcher drill as used in the army ambulance work is commonly employed. The writer's experience, however, is that a literal adhesion to the army drill is not attended by any difficulty, a company of boys even going through the movements with great precision and accuracy after two or three drills, and evincing real enjoyment in the occupation. The author, therefore, thinks it will be useful to ambulance societies and ambulance pupils to give that drill in detail.

The most suitable number to drill together is sixteen or twenty. That would be a sufficient number for four stretcher squads with four stretchers. Of course even only four would be sufficient to drill together as one squad, but it is well to drill two or three squads together in order to excite a healthy rivalry, and also to inculcate the necessity of all working together, not only the members of one squad working as one man, but all the squads keeping together as one man.

Formation of Company for Stretcher Drill.

The instructor takes up his position opposite the place where he wishes the right-hand man of the line to stand, and gives the command

Company—fall in.

Whereupon the men take places in succession, the man at the right-hand end of the line taking his position directly facing the instructor, and two paces in front of him, the remainder falling in one after the other in line with the first and on his left. Each man as he falls in takes up the position of attention, already fully described on p. 761, the elbows being slightly turned outwards. When all are properly in line each man should be able to feel his right or left hand man at the elbow, and to see the lower part only of the face of the second man from him on either side, by turning his eyes to one side or other, but his head being kept unmoved. The line is now

to be "sized", that is to say, the men will be caused to change their position in the line, the tallest man being placed on the extreme right, and the shortest at the left end of the line, the remainder occupying a position in the line according to their size. This is done by the following orders:—

Number.

Upon this the right-hand man calls out "one", the second man "two", and so on down the line.

The instructor will then form the company two deep in the following manner. He will first give the order,

Odd numbers one pace forward, even numbers one pace step back—march.

Whereupon numbers 1, 3, 5, 7, &c., down the line step forward one pace, numbers 2, 4, 6, 8, &c., down the line step back one pace.

The instructor next cautions No. 1 to stand fast, and commands

Ranks, right and left—turn.

With the word "turn" the front rank (the odd numbers) turns to the right, except No. 1, who still keeps facing the front; the rear rank (the even numbers) turns to the left. In this position the front rank is facing to the right, and the rear to the left.

The next order is

Form company; quick—march.

At this command No. 3, the second man of the front rank, marches up and places himself behind No. 1, and two paces (60 inches) in rear. The next front-rank man, No. 5, marches up to the left side of No. 1, where he halts and turns to the front. The next front-rank man, that is No. 7, marches up behind No. 5, and is thus in line and on the left of No. 3. Meanwhile the remaining men of the front rank are marching up, and are taking their position alternately in the front and reak ranks, as already described for Nos. 3, 5, and 7, and the rear rank is marching down behind the front rank to tail in with and follow up the last man of the front rank, and to take position, one to the front and the next to the rear, as already noted.

In marching up, the front-rank men form first one to the front, the next to the rear; but the rear-rank men form up, the first to the rear, the next to the front.

When this movement is completed the company is standing, in the position of attention, in line, two deep, and the shortest men are in the centre, and the tallest on each side of them.

The instructor then gives the order

Right—dress.

n

The right-hand man of the front rank stands fast, and the others glance towards the right, without moving the head, and shuffle forwards or backwards till each man is so in line that he is able to distinguish just the lower part of the face of the second man beyond him.

It is to be noted that in stepping forward or back, the step is begun with the left foot, which is carried forward or back a distance of 30 inches, the man's body being kept all the time perfectly erect. When the left foot has touched the ground, the right is carried forward or backward to be in position of attention, heels together, toes pointing outwards, and the feet forming together an angle of 45 degrees.

Each set of two, a front-rank and a rear-rank man, forms a file, and 8 files will thus contain 16 men in two lines of eight men each.

In the event of the company consisting of an odd number, the position third from the left end of the rear rank is left blank.

The company is again numbered *in files* by the command

Company—number.

The man on the extreme right calls out "one", the man next to him (in the front rank) "two", and so on down the line, the rear-rank men not calling out at all, since the number of their corresponding front-rank men apply to them.

The company having been thus formed two deep and duly sized, each man must remember his relative position in the company, and when at the next exercise the company is ordered to fall in, each man must quickly and quietly take his post, noting that he is in the proper attitude of attention and accurately in line with his neighbour.

Formation of Stretcher Squads.

The company has been drawn up, standing in line, two deep, as already described, and the files have been numbered from the right down the line to the left, so that the first or right-hand file is No. 1, the second file (on the left of No. 1) is No. 2, and so on. This numbering must be noted in explanation of what is to follow, where we shall have to speak of the files with odd numbers as "odd files" or "right files", and the files with even numbers as even files or "left files".

The instructor gives the command

Form—fours.

On the word "fours", the left or even files, that is Nos. 2, 4, 6, 8, &c., will step back 30 inches to

the rear with their left feet, and immediately thereafter 27 inches to the right with their right feet. The result of this is that, considering for the moment only files 1 and 2, these two files form together a squad four deep, in which the front man is the front-rank man of No. 1 file, the second man is the front-rank man of No. 2 file, the third man is the rear-rank man of No. 1 file, and the fourth man is the rear-rank man of No. 2 file, and the company of 8 files is now standing in 4 squads, each four deep, separated by intervals from one another.

Each squad of four deep is called a stretcher squad, and each member of a squad is called a bearer.

In the further drill of a stretcher squad, it is necessary to give each bearer a number for purposes of identification. The bearers in the front rank are called No. 1 bearers, those in the second rank No. 2 bearers, those in the third No. 4 bearers, those in the rear rank No. 3 bearers. This is intimated to the squads by the instructor in the following words:—

Front Rank. No. 1 Bearers—stand at ease.

At the word "ease" the front rank down the line of squads takes up the "stand at ease" position, described on p. 761. Then the instructor proceeds

Second Rank. No. 2 Bearers—stand at ease.

Again on the word "ease", the second rank takes up the proper position, so the instructor proceeds

Third Rank. No. 4 Bearers—stand at ease.

Fourth Rank. No. 3 Bearers—stand at ease.

All the bearers having thus been shown what their numbers are, the instructor brings the squads to their former position by the command

Company—attention.

He may repeat this till every one knows his number as a bearer, and at once responds to his own number.

The next thing is to number each of these squads in order from the right. The instructor orders

Number—the squads;

and the front-rank man of the right-hand squad calls out "one", the front-rank man of the next squad calls out "two", and so on.

Exercising Squads with Stretchers.

Previous to the drill being begun, the stretchers are laid in a heap on the ground. The No. 3 bearers should now be marched to the heap, each No. 3 taking a stretcher for his squad. This is done by the following commands:—

Nos. 3—right (or left) turn.

All the Nos. 3 turn as ordered, right or left being ordered according to the position of the heap of stretchers. The next order is

File on stretchers—quick march.

On the word "march", the Nos. 3 step off, one behind the other, keeping step, the leading man taking the nearest way to the stretchers. When the stretchers are reached, the leading man picks up one and places it, at the slope, on his right shoulder, rollers to the front. He then marches on to give room for the other bearers to come up, each in turn, and secure a stretcher. When he has marched on sufficiently far, the instructor should give the order

Mark time in front.

When the last bearer has secured his stretcher, the instructor should order

About turn—forward;

whereupon the bearers should turn about and march back, still in file, but the bearer who was last now leading, till the squads are reached, when the bearers should march in, each to his proper place. The instructor then gives the orders

Halt. Front.

The instructor now gives the order

Lower—stretchers,

when the Nos. 3 take the stretchers from the shoulder and lay them on the ground on the right of the squad, passing what, at the slope, was the lower end to the front, rollers to the right of the squad. The next command is

Stand to—stretchers;

whereupon No. 1 sees that his toes are in line with the front end of the poles, No. 3 that his heels are in line with the rear end, No. 2 that he is one pace in rear of No. 1, and No. 4 one pace in front of No. 3, all touching the stretcher with the right foot.

The squads are next to be exercised lifting, marching with, and lowering stretchers.

On the command

Lift—stretchers,

Nos. 1 and 3 (the front and rear men) stoop down and take hold of the handles of both poles with the right hand—rollers away from them—and rise to attention together, holding the stretcher at the full extent of the arms.

In stooping, the men must keep the knees straight; the rear bearer must time his movements with those of the front-rank man, and the men of succeeding squads must time their movements with those of No. 1 squad, so that all the squads act together as one man.

On the command

Lower—stretchers,

Nos. 1 and 3 stoop down, place the stretcher on the ground and rise to attention together, again all squads acting together, taking time from No. 1.

Marching with Stretchers.

The squads are now made to lift stretchers and practise marching in close order, the following being the commands:—

Lift—stretchers.

If several squads are drilling together, they are caused to dress up in line with one another and at proper distance from one another (27 inches) by the command

Right (or left)—dress.

The No. 1 of the flank squad named (right or left) stands fast, the Nos. 1 of the other squads look to that flank and move up or back to get into line, the other bearers look straight to their front and get accurately behind the bearers in front and at proper distance. The dressing being finished, the instructor gives the order

Eyes—front,

when all look straight to the front. This being done, the instructor calls out

The Company will advance. By the right (or left), quick—march;

whereupon the squads all start off with the left foot, keeping in line with the squad named, that on the right or left as the instructor happens to order.

When the company is on the march, at the command

The Company will retire. About—turn,

the bearers of each squad will turn about towards the stretcher, Nos. 1 and 3 transferring it from the right to the left hand at the same time. When retiring the company is made to advance by the command

The Company will advance. About—turn.

The bearers turn *towards* the stretchers as in retiring.

The squads should also be practised marching in extended order, with four paces interval between each squad. The squads having been made to lift stretchers, receive the order

From the right (left, or No. — squad), to four paces—extend.

The squad named (right, or left, or No. 2, &c.) stands fast, the other squads turn to right or left, away from the named squad, and step off in quick time.

Suppose the order has been "From the *right*, to four paces—extend", then the right-hand squad—that is No. 1 squad—stands fast, the other squads turn to the left and step off. As soon as the squad next to the right—that is No. 2 squad—has taken four paces, it halts and turns to the front. The No. 1 bearer at the moment of halting taps with his left hand the shoulder of No. 1 bearer of the next squad—No. 3 squad. That squad (No. 3) takes four paces from the moment their No. 1 bearer has been tapped, and it then halts and turns to the front, their No. 1 bearer, at the moment of halting, tapping with his left hand the shoulder of the bearer in front of him, that is No. 1 bearer of No. 4 squad. So the process would go on though twenty squads were drilling together, till the whole twenty were extended in a line at four paces interval from one another.

If the order has been to extend from the left, then the left-hand squad stands fast, and the others turn to the right and step off, the first squad from the left taking four paces, then halting and turning to the front, their No. 1 bearer tapping the No. 1 bearer in front of him at the moment of halting, and so on.

Suppose four squads drilling together, and the order to be "From No. 3 to four paces—extend", then No. 3 stands fast, the others turn away from No. 3 and step off. That is, Nos. 1 and 2 squads turn *to the right* and step off, No. 2 halting as soon as four paces have been taken, their No. 1 bearer tapping, as he halts, the No. 1 bearer of the squad in front—No. 1 squad, No. 1 continuing with other four paces before halting and turning to the front, while No. 4 squad turns to the left, steps off for four paces, and then halts and fronts.

If this movement of extension is ordered while the squads are on the march, the named squad (right or left, &c.) continues to move straight on, but with a short step (21 inches), the remaining squads make a half turn to right

or left, keeping at the full pace, and, when they have reached the proper distance, turn to the front and step short. When all the squads have reached the proper interval, the full step is resumed on the command

Squads—forward.

If the squads have been extended, they may again be brought into close order. The command is

On the right (left, or No. — squad)—close.

If the squads be halted at the time, the named squad stands fast, the others turn and march towards it at quick time, halting and fronting when the proper position is reached—an interval of 27 inches between each squad.

If the squads be on the march, when the order is given, the named squad marches straight on, *stepping short*, the other squads make a *half turn* towards it and close in upon it at quick time, each squad turning to the front and stepping short, when its proper position is reached. When all the squads have closed in, the full step is resumed on the order

Squads—forward.

To Prepare Stretchers for Use.

The squads are brought into extended order (4 paces interval) as already explained. The command

Prepare—stretchers

is given. On the word "stretchers" Nos. 1 and 3 of each squad turn to the right, kneel down on the left knee, unbuckle the straps, separate the poles, pass a hand under the traverse to make sure that it is locked. The slings are then taken and doubled, dressed side of the leather out. The loop formed by the doubling is slipped on the near handle of the stretcher, and the free ends rest over the opposite handle. Both bearers then rise to the former position, Nos. 2 and 4 meanwhile standing fast. The rear bearer keeps time with the front bearer, and those of succeeding squads with No. 1 squad. The front bearer of No. 1 squad must, therefore, make certain the other bearers are ready before he rises, so that all may rise together.

On the order

Close—stretchers,

Nos. 1 and 3 turn to the right, kneel on the left knee, remove the slings from the handles and place them on the ground, place the hand under the canvas and bend inwards the traverse, raise the canvas, so that it does not catch between the poles, bring the handles together, rise, lifting the stretcher, face one another, place the handles between their thighs, rollers to the right of the company, roll the canvas tightly round the poles (towards the right of the company). Each takes a sling, passes the buckle end to the other, threads the transverse strap through the loop of the other sling and buckles tightly, close to the rackets. Grasping both handles in the right hand, back of the hand to the right, they turn to the right of the company in a slightly stooping position. From which, all being ready, they rise together and turn to the front, taking time from the right.

To repeat this exercise the company is ordered to lower stretchers, and the orders "Prepare stretchers", &c., are repeated.

Lifting and Lowering and Marching with Prepared Stretchers.

The next exercise is in lifting and lowering prepared stretchers, and in marching with them.

The order to prepare stretchers having been given and carried out as described, the command is given

Lift—stretchers.

On the word "stretchers" Nos. 1 and 3 stoop down, grasp the doubled sling, at the centre, with the finger and thumb of right hand, remove it from the handles and stand up. Each then takes a side pace to the right over the near handle, and closes heels. Each then places the sling, equally divided, over his shoulder, with the end to which the transverse strap is attached over the right shoulder. They stoop, slip the loops of the sling over the ends of the poles, commencing with the left, and then firmly grasp the poles. After a short pause they steadily raise the stretcher off the ground, and stand up, holding the stretcher at the full extent of the arms. No. 3 must keep time with No. 1, the stretcher being kept horizontal throughout. Thereafter No. 2 takes two paces to the front, and turns to the right about, thus facing No. 1; No. 4 turns to the left about (at the same instant No. 2 turns) and faces No. 3. Nos. 2 and 4 then adjust the sling on the neck and shoulders of Nos. 1 and 3 respectively, so that it lies accurately on the hollow of the shoulder in front and is well under the collar of the coat. No. 2 then takes two paces to the rear, and he and No. 4 front together. In all these movements the bearers must act together,

turning together, &c., the time being given by the No. 1 squad.

In the early practice of this exercise, these movements are timed by the instructor calling out "one", when the bearers begin the movements. When they have completed them as far as placing the sling on the neck, he calls out, "two", when they stoop and adjust the slings on the poles; and "three", when they should rise together. But after some practice, the bearers must judge the times themselves.

On the order

Lower—stretchers,

Nos. 1 and 3 lower the stretcher to the ground, slip the loops off the handles, stand up, remove the sling from the shoulders, double and hold it in right hand between fingers and thumb, then resume the original position at the side of the stretcher by taking a pace to the left over the handle, stoop down, arrange the sling on the handles as already described, and rise together.

The stretchers having been prepared as described, and lifted, the squads are to be practised marching with them.

On the order

By the centre—advance,

Nos. 1 and 3 step off immediately, No. 1 with the left foot, No. 3 with the right, *so that the step is broken,* and no side-to-side movement communicated to the stretcher. Meanwhile No. 4 turns outwards (to the left), moves smartly round the rear bearer, and up to the centre of the opposite side of the stretcher, while No. 2 marks time one pace, and is thus opposite the centre of his side of the stretcher. Nos. 2 and 4 keep step with No. 1.

It is very important to see that the bearers so march with prepared stretchers that no jolting would be suffered by a wounded man borne by them on the stretcher. This is best secured by them taking a short step of 20 inches, the knees well bent, the feet being raised little off the ground, the step being broken, as already noted, and the stretcher being kept horizontal.

On the order

By the centre—retire

with prepared stretchers (or on the order "Advance", when the squad is retiring) the squad will wheel by the right to the rear (or front), No. 3 simply marking time, and slowly turning till the wheel is accomplished.

On the order "Halt" Nos. 2 and 4 resume their old positions, No. 2 taking one pace to the front, and No. 4 turning outwards and doubling round the head of the stretcher to his old place on the left of the stretcher.

To Load or Unload Stretchers.

To practise loading and unloading stretchers, men to represent wounded are caused to lie down, the head towards the company, ten paces in front of the company and extended four paces from one another. The squads, standing in close order with stretchers lifted but closed, receive the order

Take post at the right of wounded—advance.

Each squad moves to its patient and halts without further command two paces on the side indicated and in line with him. The following commands are then given:—

Lower—stretchers,
Prepare—stretchers,

and acted on as already described.

The next order is

For loading, lift—wounded.

Nos. 1, 2, and 3 wheel round by the patient's feet, and march up on his left side (No. 3 passing by the left of No. 4), No. 1 halting opposite his shoulders, No. 2 opposite the hips, and No. 3 opposite the knees. They turn towards him together, No. 4 then placing himself opposite No. 2, that is next the patient's hips. All kneel on the left knee. No. 1 passes his right arm beneath the patient's right shoulder and his left across the patient's body, his left hand being passed under the patient's right shoulder. Nos. 2, 4, and 3 pass their arms, close together, under the patient's loins, hips and knees respectively. If the patient is able, he places his arms round the neck of No. 1 bearer, clasping his hands. The bearers, as one man, slowly lift the patient 24 inches off the ground, resting him on their right knee. No. 4 relinquishes his hold, doubles round by the head of the stretcher to the centre of the opposite side, grasps the near pole with his left hand and the farther one by his right, lifts the stretcher and places it directly under the patient. He then kneels and helps to support the patient.

The instructor now gives the command

Lower—wounded.

The bearers gently lower the patient on to the stretcher, remove their hands from under him, special care being taken of any wounded part. They then stand up, and resume their former

position in line on the left of the stretcher. To do this Nos. 1, 2, and 3 turn to the right, and wheel by the right to their places, No. 1 at and to the left of the patient's feet, No. 2 behind him, &c., No. 4 meanwhile turning to the left, and wheeling round the head of the stretcher by the left of No. 3 to his place behind No. 2.

The order is then given

Lift—stretchers,

and is carried out in the manner already described for unloaded stretchers. The squads are to be practised advancing and retiring with loaded stretchers, as they did with unloaded stretchers, the bearers marching with short broken steps to prevent jolting and injury to the patient, as already directed. This is made easier if the bearers are as nearly as possible of equal height. On sloping ground the general rule for bearers is to carry the foot end of the stretcher foremost down hill, and the head end foremost up hill. On halting and lowering stretchers, the bearers must take great care to prevent jolting.

The squads having been halted and the stretchers lowered, the command to unload the stretcher is given thus:

For unloading—lift wounded.

No. 4 turning outwards (to the left) doubles round the head of the stretcher to the centre of the opposite side, and the whole turn to the patient together, No. 1 placing himself opposite the knees, No. 2 opposite the hips, and No. 3 opposite the shoulders of the patient. They then proceed to lift the patient to their knees, as already directed. No. 4 grasps the stretcher, as before described, steps back two paces, places it on the ground, doubles back to his place round the head of the stretcher, and resumes the support of the patient.

The instructor then orders

Lower—wounded.

The patient is lowered, the bearers disengage and stand up, resuming their proper places at the left of the stretcher as follows:—All turn to the left, Nos. 1, 2, and 3 wheel by the left round the head of the patient to their places, No. 1 at the foot and to the left of the stretcher, &c., No. 4 falling in between Nos. 2 and 3.

The completion of the exercise is effected by the following commands:—

Close—stretchers.
On the right—close.
Lower—stretchers.
About—turn.

On the last order the bearers turn about, and on the further order

By the right—quick march,

they march off, leaving the stretchers on the ground.

When they have marched clear of the stretchers, they are ordered to halt, and immediately after the order is given

Front.

Whereupon the bearers, at the moment standing four deep facing the rear, turn together to the front and immediately form up two deep, by the Nos. 2 and 3 of each squad taking a pace of 27 inches to the left with the left foot, and a pace of 30 inches to the front with the right foot. This brings them into the formation described on p. 1036, before the formation of fours.

The next commands are

Right—dress (see p. 1036); **Right—turn,**

when the men will turn as directed. Finally on the order

Dis—miss,

the front rank will take a side pace to the left, and the rear rank will take a side pace to the right. After a pause the company will break off quietly.

Equipment of a Stretcher Squad.

Besides a stretcher, each squad should be provided with a water-bottle, and a haversack containing splints, bandages, a tourniquet, scissors, and safety-pins.

No. 2 bearer carries the water-bottle; No. 4 carries the haversack. The water-bottle hangs on the left hip, sling over the right shoulder, the haversack hangs on the opposite side.

A CHAPTER ON SICK-NURSING. MEDICAL AND SURGICAL APPLIANCES.

The Duties of a Sick-Nurse.

The Qualifications of a Sick-Nurse:
The Dress of the Nurse.

The Sick-Room:
Its Cleanliness; Its Ventilation; Its Warmth.

The Sick-Bed:
Changing Sheets, &c.

The Sick Person:
The Diet—**Its Frequency, Quantity, and Method of Administration;**
The Administration of Medicines;
Clothing—**Changing Clothing;**
Discharges—**Bed-pans;**
Bed-sores.

Medical and Surgical Appliances:
Syringes, Inhalers, Nasal Douche, Catheter.
Fomentations and Poultices.
Leeches and their Application.

A Few Recipes for Sick-room Cookery.

The Duties of a Sick-Nurse.—It is an old notion that any woman who has reached, or perhaps still better, has passed, the prime of life, who has borne a large family, whether she has reared them well or not does not matter, who "has seen a lot of trouble," who has witnessed numerous death-beds, is very well qualified to be a nurse. She is "a woman of experience," and this kind of experience enables her, it is supposed, to act with authority and judgment in the sick-room, whatever be the nature of the disease the patient is suffering from, and whatever may be the emergency that arises. There never was a greater mistake than this; there is none more productive of evil to the patient. It is the same mistake which causes people to speak of the duties of the nurse, in contradistinction to the duties of the doctor! In the care and treatment of the sick the view, on which this mistake is based, supposes that the doctor has one well-defined limit of duty, and the nurse another, and the doctor must not trench on the nurse's province, lest he offend her. A nurse who takes up such a view makes a fatal mistake. She must begin her work with the idea firmly implanted in her mind that she is only the instrument by whom the doctor gets his instructions carried out; she occupies no independent position in the treatment of the sick person.

It is the doctor's business, and his only, having carefully inquired about all the facts relating to his patient's case, having thoroughly examined his condition, observed and considered all the symptoms, and having come to a conclusion as to the nature, and, if possible, cause of his illness, it is the doctor's business then to determine not only what medicines, if any, he will order for the sick person, but also what are the conditions under which the patient ought to be placed to enable him to wrestle with the disease under the circumstances most favourable for his recovery. He is bound to consider, that is to say, not only what medicines he will order, but also what food and drink are most appropriate for his situation, what kind of atmosphere he ought to breathe, what degree of heat that atmosphere should have, and every other circumstance that will aid his natural tendency to recovery. It is his business also to consider whether the surroundings of the patient are the best possible to conduce to this end, and if not, how they may be improved, so far as improvement is within the patient's power. Having arrived at his conclusions, it is then his duty to give his instructions to the nurse, to prescribe the medicines, to indicate the nature, amount, and frequence of the diet, how the patient is to be placed and covered in bed, to indicate how the apartment is to be kept as regards air and heat and light, and so on. It is the nurse's business carefully and accurately to note these instructions, not in a mere general way, but in every minute detail, to make certain that she understands the instructions given, and having received them, strictly but intelligently to act upon them and carry them out to the letter.

This is very different from the old notion that it was the doctor's business to come in, examine the patient, write a prescription, and walk off, leaving everything else to the nurse, as her business.

The first thing that is implied in this explan-

THE ARRANGEMENT OF THE SICK-BED.

THE ARRANGEMENT OF THE SICK-BED.

I. The bed is made in the ordinary way. Across the centre of the bed, thus made, is laid a waterproof sheet, and above that is laid the draw-sheet, an ordinary sheet folded once. One end of this draw-sheet is pinned down as shown in the illustration, and this leaves a long end at the other side of the bed, which is folded up to obviate soiling. When the part of the sheet under the patient has become soiled, a fresh piece can be substituted by drawing the sheet through from the short side.

II. To change the draw-sheet when the patient cannot be moved from bed, the pins fixing it are undone; to one side a fresh draw-sheet is pinned; and then one nurse, by slipping her hands under the patient's body, eases up the patient sufficiently to permit the nurse on the other side to draw through the soiled draw-sheet, which, of course, drags after it the fresh sheet attached to it.

I. The bed-clothes folded over to show the draw-sheet pinned down on the top of the ordinary sheet.

II. The draw-sheet being changed.

ation of a nurse's duties is that she, as a nurse, has no responsibility whatever beyond the responsibility of carrying out her instructions. In the treatment of a sick person there can be no divided responsibility; if there is, so much the worse for the patient. The whole and undivided responsibility of directing the treatment belongs to the doctor, the nurse is responsible only for executing the directions, not in any degree for their nature or their results. This ought to be considered by her as a great relief, a great guarantee of security, provided always, and only, that she conforms to her instructions. The second thing implied in this explanation of a nurse's duties is that she, as a nurse, has no "opinions," no "thoughts." It is not an uncommon thing for a patient, or a patient's friends to say, "What is your opinion, nurse?" If she is a well-trained nurse she will, in effect, reply, "I have no opinions on the subject;" and she cannot more thoroughly demonstrate her want of qualification and suitability for the work she has undertaken than by launching into a long account of her experience when attending Mr. So-and-so, or of what happened in an exactly similar case she had, &c. It is also not an uncommon thing for a doctor, asking an explanation of some order being left undone, to be told that it was just about to be done, when, on account of something else "nurse thought," &c. The nurse must have no opinions and no thoughts, we repeat. If it is impossible for her not to think, and impossible for her not to draw conclusions from her thoughts, she must, at any rate, keep them securely locked up in a remote corner of her mind, where they will not interfere with her execution of the orders she has received. The general in command of an army confronting the enemy moves his troops in accordance with a plan of action in his mind. He orders his officers to move their battalions in accordance with his plan, and the duty of his officers is to obey the orders they receive. If every or any captain thinks he is entitled to carry out the order he has received only so far as he deems fit, or to alter it to what he thinks better, the plan of action will be upset and the battle may be lost. So the doctor, in his fight with disease and death, marshals his forces of medicines, food, drink, and so on, in accordance with a plan in his own mind, and if the nurse whose duty it is to carry out his instructions, thinks she is entitled to modify them or set them aside, the odds against the patient are all the heavier.

A second part of a nurse's duty is to observe. In many cases of disease various changes occur within twenty-four hours, the knowledge of which would be of great value to the attending physician, and which it is impossible for him to acquire by the daily visit or by the morning and evening visit. For instance, at one period of the day there may be an undoubted rise in the heat of the body. This may recur at or about the same hour every day, but there may be no evidence of it whatever at the usual hour of the doctor's visit. It is quite clear that if this were noted by the nurse and reported to the doctor, it would be a fact of much value. Or there may be spasmodic attacks of discomfort, or pain, or breathlessness, and so on. All such circumstances it is the duty of the nurse to observe and report. But she must beware of reporting anything but the bare facts. She is apt to have her own explanation of the facts she has observed, and to colour her report in accordance with her own idea of their meaning. It is necessary, therefore, for her to train her powers of exact observation, and to exercise herself in the task of reporting exactly what occurs without alteration or addition.

What, then, are the chief points a nurse has to include in her report to the doctor at his visit? She will have to inform him (1) as to the food and drink the patient has taken, since his last visit. This she must be prepared to detail as to its actual amount, and times of administration, as well as its nature. Thus her answer should run something like this: "At mid-day yesterday he had a breakfast-cupful of beef-tea and a quarter of slice of toast. At 2 afternoon another breakfast-cupful of beef-tea and half a slice of toast; at 4 half a tumbler of milk; at 8 —," and so on. And then she should be ready to sum the whole up in some such way as this: "In all, since yesterday at 12, he has had 4 pints of milk, $\frac{3}{4}$ pint of beef-tea, 1 egg, 2 slices of bread, and 4 biscuits." The doctor would then, it is evident, have a clear idea as to whether sufficient nourishment were being given or not.

(2) The second part of the nurse's report should be as to her administration of medicine, the amount given, the hours at which it was given.

(3) The nurse should be ready to state *exactly* —in hours and minutes—what sleep the patient has had, and whether the sleep was quiet and sound, or light, or troubled and restless, and so on.

(4) The nurse ought to be ready to inform the doctor as to the emptying of the bladder

and bowels, how frequently and at what hours these acts were performed. She should have noted in relation to the urine, the quantity and colour, and in relation to the motions their size, colour, consistence, whether formed or semi-liquid, whether uniform in appearance or mottled with patches of white, &c.

(5) The nurse should have observed and noted any other circumstances that may have occurred, such as sweating, coughing, spit, vomiting, delirium or wandering, excessive thirst, headache, or any other pain complained of. As regards cough and spit, she should be ready to state the time of their occurrence and recurrence, and should have preserved in a covered mug some of the spit for the doctor's inspection. As regards the vomiting she ought to be able to state when it occurred, how it was related in point of time to the giving of food or medicine, what it was like, and should have preserved some, *but not in the sick room*, for the physician's inspection.

A nurse cannot be expected to carry all these things in her memory, and therefore they should be noted down in writing. All this will be best done by the nurse, before assuming duty, providing herself with a note-book, not a tiny penny diary, but a sensible note-book, say about 7 inches long by 4½ broad, by ½ thick. She should rule a straight line down the outer edge on one side, giving a space sufficiently broad for marking the time, and a second broader space on the inner side for "Remarks." One page may stand for a day of 24 hours, or if the case makes frequent notes necessary, one page may note the occurrences from say 9 A.M. to 9 P.M., and the following page from 9 P.M. to 9 A.M. Then down the page are entered the facts as to food, medicine, &c., the hour being stated in the narrow outer column. At the head of each page the date would be entered. The doctor would likely enough take advantage of such a note-book to record the results of his observation of temperature, pulse, and breathing. Thus in the note-book one would have almost a history of the case and always an accurate record of its progress. One page of such a note-book would have something like the following appearance:—

MARCH 10th.		REMARKS.
9 a.m.	Small dessert-plateful of porridge and a tumblerful of milk.	
10 ,,	One tea-spoonful of medicine given.	
10.30 ,,	Two wine-glassfuls of milk and soda.	
11 ,,		Patient asleep from now till 11.45.
12 noon.	Tea-cupful of beef-tea, ½ slice toast.	
12.15 p.m.	Temperature 103° / Pulse .... 118 / Breathing ... 24	Dr. called. Medicine to be given every 2 hours till further orders.
12.30 ,,	One tea-spoonful of medicine.	
1 ,,		Water passed, about ½ pint—very high coloured.
2 ,,	Tea-cupful beef-tea, ½ slice toast.	
2.30 ,,	One tea-spoonful of medicine.	
3.45 ,,		Patient slept from 2.45 till now; quiet deep sleep.
4 ,,	Half a tumbler of milk and two wine-glassfuls soda-water.	
4.30 ,,	Tea-spoonful of medicine.	
6.30 ,,	Tea-spoonful of medicine.	Profuse sweating for ½ hour.
7 ,,	Tumbler boiling milk, one slice toast.	Clothes changed.
8 ,,		Bowels moved freely—natural.
8.30 ,,	Tea-spoonful medicine.	
9 ,,	Half tumbler of milk and soda.	

It may be, and very often is, necessary for the nurse to prepare as well as administer the food of the patient. At anyrate she should be ready for such a circumstance if it arises. Therefore she should be able to cook, to prepare little dishes plainly but palatably; and she should take pains to acquire a knowledge of a variety of ways of cooking the same thing, so that she may tempt a patient's appetite or excite it. The sick man's stomach rebels against a diet from day to day everlastingly the same. And besides ministering to the feeble appetite by a dainty morsel of one kind or another, the nurse may coax a patient to try what she has prepared, by the cleanness and neatness with which it is set before him.

The Qualifications of a Sick-Nurse.—If such as have been stated are the duties of a sick-nurse, it will not after all be an easy task to fulfil them thoroughly. The qualifications for the post will be manifest. Intelligent, painstaking, careful, exact, methodical, all these are very necessary qualities in the nurse. She must be scrupulously clean and tidy in all her ways. If so the sick-room will be clean and orderly, so also will the sick-bed be. In her person she will also be clean and neat. One thing is very important. Her breath must not be foul-

smelling; and to ensure this she will do well regularly to use tooth-powder and mouth-wash (see recipes No. 85 and 81). Besides all this many other qualities are needed, pleasant manners, deftness and gentleness of touch, patience, quietness of manner, &c. All her work must be done without fuss or noise, and without the manner that is perpetually drawing attention to all she is doing. One thing a nurse must not be —a gossiper or chatterer. She may beguile a little time talking if the patient desire it, but it must not be with tales of her experiences, and accounts of the sick-beds of others, their sufferings and doings. His own symptoms and ailments and prospects are not to be referred to at all. Any information he desires on these points must be supplied by the doctor.

The Nurse's Dress and Behaviour.—It has been already said that the nurse should herself be scrupulously clean and tidy. Her dress should be of soft material that will not rustle, of a quiet colour, not black. It should be of material that will wash. A white apron with bib, a pair of close-fitting linen cuffs, and a white cap are also usual and desirable. She should wear soft slippers that make no noise as she moves. She should go about the sick-room quietly but with a decided step, not shaking the floor with her movements, but equally not sneaking about on tiptoe. She should speak in her natural voice, but quietly. Whispering is not permitted in a sick-room. A whispered conversation carried on outside his half-open door is to a patient particularly exasperating. All her own dressing the nurse should do outside of the sick-room. Her meals also should all be taken outside in some other room. When she is occupied about the patient her hands should be warm but dry. A cold hand, or a moist clammy hand, is an abomination. She can warm her hands with hot water, thoroughly drying them thereafter. If she is sitting in the sick-room, she will occupy herself with some light work or otherwise. But she must take care not to be unconsciously an annoyance. Sick people are so irritable, that the smallest thing is sufficient to disturb them. The rustle of a newspaper, or turning over the leaves of a book, the monotonous click of knitting-needles, the swing of a rocking-chair, or creaking of a wicker chair, all these may be seriously disturbing.

The Sick-room.—The sick-room should be, if possible, large, especially ought it to be so if the case is likely to be a prolonged one. It is a practical impossibility to ventilate without draughts a small room, and nothing is of greater consequence in the proper tending of the sick than the maintenance of a *constantly* pure atmosphere. All excess of furniture should be removed, as it simply takes up air-space. While it is well for the pleasure of the patient to have the room as bright and tidy as possible, it is undesirable to have much of the nature of ornaments and hangings, since they harbour dust. The wash-stand should be kept constantly clean and free from accumulations of glasses, cups, bottles, and all the odd etcetera of a sick-room with which it is usually littered. A small table should stand by the bedside, within easy reach of the patient's hand. The most it should ever hold should be a glass with a few flowers, perfectly fresh, a tumbler with drinking water, perfectly clean, and very frequently renewed, and, it may be, a small tumbler containing milk and soda or milk and ice. If ice is allowed the patient, the glass of drinking water may be replaced by a tumbler, covered with a piece of new well-washed flannel containing small pieces of ice, as shown on Plate XIX., fig. 7. If any orange or other fruit is allowed, a few small portions ought to be prepared, set on a plate which is supported on a bowl containing some pieces of ice to keep it cool. No food should be prepared or cooking done in the sick-room. All ought to be prepared outside, brought in when required, and the remains with the soiled dishes ought to be removed again from the room as soon as the patient has been satisfied. In the same way all soiled linen, towels, handkerchiefs, &c., should be removed from the room without delay and should be at once immersed in water.

No slop water should be retained in the room, nor slop-pail; all should be immediately removed, the vessels washed outside and brought back clean. It is never desirable that a sick-room should contain a set-in basin, connected with the drainage pipes. If such exists in the room, and another room is not to be had, strict orders must be given to prevent its being used. The waste-plug should be set in and the basin kept full of water, frequently run off and renewed. Basins which have no drain connection, but are provided with a tank underneath, are, in some respects, still worse. They invariably give out a very unpleasant smell. If the whole stand cannot easily be removed, the tank ought to be, and some deodorizer (p. 395) used for the stand.

The Ventilation of the Sick-room is more important than almost anything else. It is quite customary for ventilation to be effected

once or twice a day by covering the patient wholly up, the head being covered as well, and then opening the windows for a few minutes till the air of the room has been completely renewed. This is all very well occasionally, but it cannot take the place of a constant renewal, which is necessary if the patient is to breathe a comparatively pure air. It is an absolute necessity that, since the air is being polluted every instant, fresh air should every instant be entering. This is ensured if a fire be burning in the grate. Therefore, one of the first things to be done in preparing a sick-room is to remove any ornaments in the grate, to open the damper, and to light a fire: if it be warm weather, the fire will of course be a small one. This fire will cause a constant current up the chimney and a constant stream through the room. The question is, whence is the air to come to supply this current? If the door and windows are kept close, it will create currents through every crack and crevice in door and window, and much of the common air from the house will be drawn through the room. If a way be opened for fresh air, however, it will be drawn less readily from other quarters. It will almost invariably be found best to draw down the window farthest from the bed, from the top, about $\frac{1}{2}$, or even only $\frac{1}{4}$ of an inch, or 1 inch by day and $\frac{1}{4}$ inch by night. The bed can usually be so placed that it will not be struck by any current of cold air, and the atmosphere of the room will be kept pure. A screen can, if necessary, always be arranged to ward off any such current from the bed. Instead of this the fitting in of a board to close the opening left by raising the lower sash for a few inches, as mentioned on p. 694, may be employed. If the need of continually renewing the fresh air of a room be kept in mind there will be little need of burning pastilles or sprinkling perfume, *which, it must not be forgotten, may hide a bad smell but will never purify the atmosphere.*

The Warmth of the Sick-room should be maintained regularly at the same degree. This degree ought to be accurately estimated by a thermometer, kept hanging so as to be out of reach of direct heat from the sun or from the fire. Avoid hanging it on a wall kept warm by a fireplace in it. It may be a blank wall on the sick-room side, but a fireplace may exist on the other side. The usual height at which the mercury should stand is 65°—never above 70° nor below 60°. The nurse should, however, ask the instruction of the doctor as to the exact degree. A nurse must remember that if she is ordered to keep the room warmer that does not imply that she is at once to block up all means of entrance to fresh air. It may mean the use of larger fires, but while she seeks to get a warmer atmosphere, she must take care it does not at the same time become a more impure atmosphere. Nor yet must she think that if the atmosphere of a room is cold it is necessarily also pure.

Sunlight in a sick-room is always desirable, unless special circumstances require darkness. But the common supposition that a sick-room should be a darkened room is a mistake. Sunlight is one of the best of disinfectants. Let the bed, however, be so arranged that the light does not fall directly on the patient's face, either by the use of a screen or by turning the bed.

The Cleaning of the Room should be done systematically, all the more regularly in that while the patient is in it it can never be done thoroughly. It must be done so that the patient is not disturbed, and so that dust is not raised. Screen the bed if possible while it is being done; dust the furniture with a cloth slightly damp; carry rugs outside and hang them up in the outer air for a little; remove as much as possible from the carpet by using a large cloth rung tightly out of water. This is to be passed over the whole carpet, the part under the bed included.

The Sick-bed.—There are two things to be noted in considering the position of the bed. The first is its position in reference to any possible draughts from doors or windows. Given a room with one door, one window, and a fire burning in the grate, it is quite clear that a current of cold air will set in from the window to the grate, and one also from the door to the grate. It is wonderful how often the bed is so placed as to be simply swept across by one or other of these currents. Commonly this can be avoided. At the worst a screen can be arranged to guard the bed on one side. Let the screen be a high one. It may be improvised of a clothes-horse and sheets or blankets. In such a case let the sheets reach quite down to and rest on the ground. Another point to observe is that one fold of the screen ought to pass right in behind the head of the bed. Usually the screen is simply stretched out along one side of the bed, and there is a space between the end of the screen and the head of the bed. The cold-air current will simply pour through this gap on to the upper part of the patient's body. The second thing to be noted in the determina-

CHANGING THE UNDER SHEET IN THE CASE OF A HELPLESS PATIENT.

CHANGING THE UNDER SHEET IN THE CASE OF A HELPLESS PATIENT.

I. The patient has been turned over on the right side, the draw-sheet has been lifted on one side, and, with the waterproof under it, is being held up over the patient. At the same time it holds and protects the patient. The soiled sheet is then rolled up lengthways as far under the patient's body as possible. A fresh sheet, previously aired and warmed and rolled up lengthways to the extent of one-half, is now laid down and properly adjusted on the part of the bed from which the soiled sheet has been removed, the rolled part of both soiled and clean sheets lying alongside one another. The waterproof and draw-sheet are now pinned down over them.

II. The patient is now turned over on the left side, the draw-sheet and waterproof lifted. The patient is thus caused to turn over the rolls. The soiled sheet is removed, the roll of the fresh one unrolled and properly smoothed out, and the waterproof and draw-sheet again pinned down. Thus a clean sheet has been substituted for a soiled one.

18c.

CHANGING THE UNDER SHEET IN THE CASE OF A HELPLESS PATIENT.

Plate XVIIIc.

I. The soiled sheet is rolled up lengthways close up to the patient, and the clean sheet, half of it also rolled up, placed alongside the soiled one.

II. The patient has been turned over on the other side, so that now the rolls of both soiled and clean sheets can be brought through from under.

tion of the position of the bed is the situation of the window. The patient should not be lying so as to face the window, if possible. It is always preferable that the bed should stand out a little way from the wall so that the nurse may easily get round it; and the fewer hangings there are about it the better. Valances prevent free circulation of air beneath the bed, and should be removed.

For any prolonged illness the bedding should be as follows: A hair mattress, protected on the top with a large square of india-rubber cloth. Above this is the under sheet. Then comes a folded sheet, spread across the bed so as to be under the patient. This is easily withdrawn when soiled without disturbing the under sheet and a clean one substituted. When there are discharges passed in bed the under sheet should be further protected by a layer of india-rubber cloth in the fold of the draw-sheet. Above the patient is a sheet, then the blankets, and then a covering of a clean sheet or other similar covering, but nothing heavy or cumbrous.

To Change the Sheets without Disturbing the Patient.—The upper sheet may be changed without folding down the clothes in the following way: The sheet having been warmed and aired (note: but not in the sick-room) roll it up in its breadth, then pass it across the bed at the foot under the sheet to be changed. Move it up over the patient, unrolling it as it goes till it is well up the bed. Then draw down the soiled sheet to the foot of the bed, and readjust the clothes. To renew the under sheet: Loose the soiled under sheet down the whole length of one side of the bed and fold it in a series of narrow plaits running lengthways close down by the patient's side. Take the fresh sheet, aired and warmed, and fold one-half of it in a series of plaits down its whole length. Lay the plaits of the clean sheet on the bed down the patient's side, alongside of the corresponding plaits of the soiled sheet. Push them up close to the patient, and gradually push them with the fingers under the patient's body, pressing down the mattress to allow them to pass. In this way the folds of the clean sheet are pushed under the patient and those of the soiled sheet *out from under* at the same time. Get the sheets pushed through under head, shoulders, and hips first, and then it is easy to raise the legs. Go round then to the other side of the bed, remove the soiled sheet, and spread out the clean one.

The pillows should be turned and smoothed frequently, and changed occasionally, and the patient should be helped to turn himself as a change. If he is sunk down in bed, the nurse assists him up on to the pillows again by bending over him, getting him to clasp his hands over her shoulders, while with her arms under his shoulders she assists him up the few inches that are necessary.

The Sick Person should wear an under-shirt of merino, and over that the usual night-gown. Only in the case of very delicate persons and children is a flannel gown necessary. It is always well to have two sets of clothing, one for night wear and one for day wear. The garments when taken off should be well aired in another room, and warmed when about to be put on again. The clothing may be regularly changed without raising the person in bed. The clothing to be put on, being well aired and warmed, is brought ready to hand. The person's arms are then slipped out of the sleeves of those he has on, which are removed by the feet while the fresh garments are put on over the head, and then the arms put in. If the case is likely to be a prolonged one it is well to have the clothing fastening down the front by tapes. The patient's hands and face should be sponged and the hair arranged now and again throughout the day; and the whole body may be sponged occasionally, as the doctor permits. This may be done under the bed-clothes just before removing the night garments. After the arms have been removed from the sleeves the nurse passes her hand under the clothes with a sponge well wrung out of soapy water, following with a towel. The whole body need not be done at a time, but bit by bit to avoid fatigue. It is well to guard the bed by a folded sheet with some rubber cloth in the sheet, pushed under the patient, while this is being done.

When it becomes necessary thoroughly to change the bed, and the patient cannot assist at all in the change, it is necessary either to move him to another bed pushed alongside the former one, and well aired and warmed for occupancy, or to place him for a time on a couch while his bed is being aired. To do this the assistance of three or four people is necessary. One stands at each corner of the under sheet, and the patient is lifted on this sheet, being kept covered all the time. He is then transferred to the fresh bed, and the fresh bed-clothes are rolled up in their breadth and introduced under the old ones in a roll at the feet, and gradually unrolled up over the patient. The soiled under sheet is then folded into plaits

down the whole length on one side, and gradually pushed out beneath the patient's body and removed. If another bed is not to be had, the couch is prepared and the patient lifted to it on the under sheet. The bed-clothes, mattress, &c., are then removed to another room, and there well aired near an open window. Thereafter, after being well warmed, the mattress is restored, fresh bed-clothes having been meanwhile aired and warmed are placed on the bed, and the patient is replaced, the soiled under sheet being then removed from under him.

The diet of the sick person, as regards its nature, amount, and frequence of administration, will have been prescribed by the physician. It is well, however, always to remember that where there is any difficulty getting the patient to take much food at a time, or to take it at all, an ample supply may yet be given by the frequent administration of very small quantities. A patient who cannot be persuaded to take, say, a cupful of beef-tea, even at three hours' intervals, may yet be persuaded to take half a wineglassful every half-hour. In a very large number of cases, vomiting may be overcome by the frequent administration of very small quantities. It is very often quite useless to bring a patient any quantity of food; and any nurse who gave the doctor as a sufficient reason for the patient having taken no food, that she brought it to him but he would not take it, simply declares her own want of tact and patience and management. A nurse should never ask a patient "Will you take a little food now?" "What shall I bring you?" "If I bring you a small plate of soup will you take it?" and so on. She should study her patient; prepare quietly a small quantity of what seems proper under the circumstances; and then, bringing it to him, should be able with a little firm but gentle management to make him take it. Children are more difficult to manage, but if the nurse is of the right kind, and can exercise, without force or anger, a little gentle authority, the probability is that in a short time she will be able to get the little patient to take food in a perfectly satisfactory manner.

In Plate XIX., fig. 10, is shown a simple arrangement for enabling a sick person to drink from a tumbler placed on a table beside the bed without the tumbler being moved. The india-rubber tube should be considerably longer than is indicated in the figure.

As to the giving of medicines little need be said except in the way of urging exactness in following the doctor's directions, and in measuring out the quantity ordered. The quantity should always be measured in a graduated glass, such as shown in Plate XIX., fig. 8. The figures *c* and *d* are very useful for doses measured by drops. The india-rubber cap is compressed between finger and thumb, the end is inserted into the bottle, and by releasing the pressure the medicine is drawn up into the tube; by gentle pressure the medicine is then forced out drop by drop.

Discharges and Bed-pans.—Whenever there is any risk of discharges being passed in bed, a draw-sheet with an ample piece of india-rubber in the fold should be under the patient to protect the bed, and no soiled sheet should be allowed to remain in the bed. Plate XIX. shows two forms of urinals for use in the bed; and bed-pans are a necessity. They should be warmed before use by being dipped into warm water; they should then be well dried, and the edge protected by a towel. When it is introduced the patient's knees should be well bent. After use the bed-pan should be immediately removed from the room, and after being well washed should be deprived of all smell by being washed in the acid solution noted on p. 396.

Bed-sores are the result of long-continued pressure on any part of the body, and they are specially apt to occur in persons of low vitality or in parts of the body where the nutritive processes are depressed owing to paralysis or other causes. Whenever long confinement to bed is necessary they must be carefully guarded against. In cases where, owing to the nature of the illness, the patient's susceptibilities are blunted, their occurrence must be anticipated, and regular examination of the body must be made to detect the slightest signs of their appearance. The places where they occur most frequently are those places which are subjected to the greatest degree of pressure—the heels, the lower part of the back, the prominence of the hip, the buttocks, and even the elbows. If the bed is not kept smooth, if folds are permitted to form under the patient, and specially if the skin is allowed to get soft and irritated by contact with wet clothing or discharges, a bed-sore is likely to be the result. With careless nursing great destruction of tissue may occur before the existence of the bed-sore is discovered. The part may be complained of by the patient as numb or tender or prickling, and the part looks red, or in more advanced stages livid or purple or black. A dark slough finally forms, and separates by ulceration, shreds and larger pieces being detached, till a large sore is

CHANGING BEDS IN THE CASE OF A HELPLESS PATIENT.

I. In this case the patient is able to sit up in bed. The clean bed is brought close up to the used one. The patient is lifted by two nurses, one at each side of the bed, who each pass the arm next the foot of the bed under the patient's thighs, and the other arm across the patient's back, locking the hands in each case. The patient is then lifted steadily and carried down the bed, over the lower end, and then backwards over the lower end of the clean bed and up into position.

II. This shows an easy method of carrying a helpless patient who must be kept in the horizontal position. Four attendants are required. Two poles six feet long are taken. The handle of a long broom will do, or a pole for raising or lowering windows. These are laid lengthways one on each side of the bed, and the under sheet rolled on them close up to the patient. The top sheet and one blanket are left on the patient, who is now carried, feet first, over the end of the used bed, and then, head first, over the lower end of the fresh bed.

18d.

CHANGING BEDS IN THE CASE OF A HELPLESS PATIENT.

Plate XVIIId.

I. When the patient is able to sit up in bed, she may be carried by two nurses.

II. A helpless patient, unable to sit up in bed, being carried by four nurses.

produced with ragged undermined edges, which may enlarge with great rapidity and pass deeply into the tissues.

To prevent the formation of bed-sores a feather-bed should be discarded, care must be given to keep the draw-sheet under the patient smooth, and to keep the patient constantly clean and dry. Then the parts on which pressure is exerted must receive special attention, and this long before any signs of the formation of a sore appear. They must be washed carefully with soap and water, and then thoroughly dried. Then there is to be gently rubbed into the skin pure spirit of wine, or eau de Cologne or whisky or brandy may be used. This is to be rubbed in till the skin is quite dry. The parts are then dusted with fine dusting powder; a quantity of powder is not to be put on, only enough to ensure the smoothness of the skin. The quantity should not be perceptible. Finally, pressure on the part is to be removed by the adjusting of air-cushions (Plate XIX., fig. 11), water-cushions, or pads of some kind. When a water-bed can be had it will greatly diminish the tendency to the formation of sores. The process of washing, bathing with spirit, &c., must be performed several times a day; and every part of the body carefully scrutinized at frequent intervals. If the surface appears abraded the same precautions must be carried out, and the air-pillows carefully adjusted. A lotion of 2 grains bichloride of mercury in 1 ounce of spirit is used to touch the surface. [*This is strongly poisonous.*] If a sore has actually formed, it requires the treatment of a bruised wound (p. 972). It is specially difficult to keep down fœtor; and for this purpose Condy's fluid in water, Sanitas, or some of the other antiseptics or disinfectants named on p. 910, must be freely used. The nurse must be careful that after such dressing of the wound no wet things are left about the bed, and that the clothes are made perfectly free from folds.

Medical and Surgical Appliances.

Plate XIX. contains illustrations of some of the more common appliances made use of in the sick-room. Several of these have been sufficiently referred to in the previous paragraphs. Figs. 1, 2, and 3 are all useful in various affections of the throat and chest. The spray-producer is used with any of the spray solutions mentioned on p. 919. The solution is put into the bottle, and the ball at the end of the tube is rapidly compressed and relaxed. The ball covered with netting is untouched by the hands. It is for the purpose of maintaining a steady stream. For sore throat the spray produced is useful. It may also be used for diffusing antiseptic solutions through a sick-room, or for spraying bed or body clothing with disinfecting solutions, or for diffusing perfume. It is also called an **atomizer.** Fig. 3 shows one kept working by steam. One fills the tin over the flame with water through the tube projecting above the handle. The solution —cold—is put in the bottle. This is used as an inhaler for inhaling medicated solutions. The person applies his mouth to the small end of the funnel-shaped piece, and breathes in the steam, which may be impregnated with terebene, eucalyptol, &c., by adding to the water in the bottle a few drops, 5 or 10, of any of these substances. Coghill's inhaler, fig. 2, is employed in lung affections. Between the double perforated wall is laid a piece of lint, cut to fit, and of a size large enough to cover all the openings. Five or ten drops of terebene or similar substance are sprinkled on the lint; the two parts are then pressed together, and the inhaler is put over the mouth, the band being fixed at the back of the neck. The person inhales by the mouth and breathes out by the nostrils. Maw's inhaler is shown in fig. 4. The vessel is half-filled with boiling-water, 5 or 10 drops of the eucalyptol, a tea-spoonful tincture of benzoin, or other material, are dropped in, the stopper is put in, and then the patient applies his mouth to the side piece and inhales the medicated steam. Fig. 5 shows an old form of enema syringe; the form commonly used is seen in Plate VIII. The **nasal douche** (fig. 6) is an arrangement of great value in treating chronic discharge from the nostril. It consists of 2 or 3 feet of india-rubber tubing of the size used for feeding bottles. At one end is attached a conically-shaped piece of bone or vulcanite with a channel bored through it for a nose-piece. At the other end is attached a piece of glass with a bend which dips into a glass of water, the bend passing over the edge of the glass. The glass is filled with the solution to be used for washing out the nostrils, and is set a foot or two above the head of the person, who applies his mouth to the nose-piece end, and by suction fills the india-rubber tube. The tube is now a syphon, and the water will continue to flow till the lower end of the tube in the glass is uncovered, or till the nose-piece end is raised up to the level of the glass. The flow being established, the person pinches the india-rubber tube to arrest it, till the nose-

piece is adjusted. It is fitted into the *healthy nostril*, and the tube released. The person slightly stoops over a basin, and the water passes up one nostril to the back of the throat, flows into the posterior opening of the other nostril, down which it flows, washing the nostril, and is caught in the basin. Just at first the person will find a very little difficulty in preventing the water passing down the gullet, but by keeping the mouth open, and raising the palate by an action the person will speedily learn for himself, all this is prevented, and the washing process quite easily accomplished. A good solution to use to a pint of water is half a tea-spoonful of salt and the same quantity of bicarbonate of soda.

A catheter is not shown in the figure. It is an instrument for passing up into the bladder to draw off the urine. The only kind of catheter a patient should use on himself is a soft, flexible catheter, preferably the Mercier catheter, one with a bend near the point. The catheter is first dipped into warm water to make it quite flexible; it is then oiled with the finger, not dipped into oil, and then the person takes a short hold of the instrument and passes it gently into the urinary opening, passing it in bit by bit. After use it should be thoroughly cleaned by allowing warm water to pass through it. No one can do harm by using a flexible catheter, while a metal instrument may do very serious mischief in the hands of an unskilled person.

Fomentations.—Make a thick pad of flannel of the desired size, place it in a basin of boiling water, and when it is quite hot lift it out by means of a stick and throw it into a large towel. Let two persons seize the ends of the towel, one at each end, and twist them up, so wringing it and the flannel within it tightly. Apply it over the part, and cover it over with oiled silk or a thick pad of dry hot flannel. When frequent fomentations are needed, a potato steamer (Plate XIX., fig. 13) may be used for keeping them ready for use. A hot-water bottle is a convenient means of applying dry heat. It should always be enveloped in flannel to guard against burning, and the same with hot bricks, &c.

Poultices.—A poultice is usually made by heating a bowl with boiling water, placing in it the desired quantity of linseed-meal, pouring on boiling water and stirring till the required consistence is obtained. It is then spread on the cloth and covered by a layer of muslin, and applied as hot as can be borne. The writer has found that the number of people who can make a good hot poultice in this way is limited; and a half-cold poultice is worse than useless. On that account the directions he gives are as follows: Take a piece of flannel considerably longer than the poultice is to be, lay it on a board, an ironing board for instance, and set it in front of the fire to warm. Set a large dinner plate on the hot plate of the stove. Have a large basting needle and thread ready, also a piece of muslin to cover the face of the poultice; unfasten the patient's clothing so that everything is in readiness. Put the linseed-meal and water into a pot and bring to the boiling point, as one would do with porridge. When the mixture is of the consistence of porridge take off the pot, and pour the mixture on to the middle of the flannel; with rapid movements of a knife or spoon spread it evenly on the flannel to the desired size, and not too thickly. A very thick poultice is also very heavy. Lay over it the piece of muslin, fold down the edges of the flannel over the sides of the poultice, and quickly run a basting thread right round. Then double the poultice on itself, place it on the heated plate, cover it with warm flannel, and carry it to the patient. It will be so hot that there is plenty of time to adjust it. Place it on the desired part, cover with the piece of warm flannel, and fix it on firmly by a flannel binder. Remove it before it is cold. If it is not to be renewed, it may be slipped out from below the binder without disturbing anything else. For a mustard poultice the writer advises the same method. The linseed is put on the fire, and, when ready, a layer of it is spread on the flannel the desired size, but with only half of the linseed porridge. To the remainder in the pot the mustard is added, and, without putting the pot on the fire again, the two are thoroughly mixed. This mixture is now spread on the top of the first layer. That is to say, the poultice is in two layers, the layer next the flannel is without mustard, the layer above it is mixed with mustard, and is the layer that goes next the patient. The muslin is then laid on, and the rest of the process is as before. The usual quantity of mustard is 1 of mustard to 3 of linseed-meal, or equal parts of each. **Bran poultices** are made as linseed-meal poultices. **Bread poultices** are made with bread crumbs in sufficient quantity over which boiling water is poured till a sufficient consistence is obtained, the whole being thoroughly mixed into a soft mass. **Charcoal poultice:** Take 4 ozs. bread crumbs, 3 ozs. linseed-meal, 1 oz. powdered charcoal, 1 pint boiling water.

APPLIANCES FOR THE SICK-ROOM.

Plate XIX

1. Spray Producer.

2. Coghill's Inhaler for antiseptic vapours.

3. Adams' Inhaler — Spray produced by steam.

4. Maw's Inhaler.

5. A form of Injection Apparatus.

6. Arrangement of india-rubber tube and nose piece for washing out the cavity of the nostrils by a stream of water medicated or otherwise from a vessel placed above the person.

7. Arrangement of glass for holding ice.

8 & 9. Medicine Measures. a tea spoon and table spoon doses. b. c. d. drop measures.

10. India-rubber tube and mouth piece attached by a clip to a tumbler to enable a sick person to drink without raising the head or moving the tumbler.

11. Air-Cushion for relief of bed-sores.

12. India-rubber Bag for the application of Ice to the head chest &c.

13. Potato Steamer. A means of supplying cloths for fomentations.

14. Bed Urinal for males. 15. for females.

Mix the bread, meal, water, and half the charcoal in a warm bowl, spread on warm flannel, and sprinkle the remainder of the charcoal on the surface. It is used to disinfect and remove fœtor, for foul sores, bed-sores, &c.

Leeches are employed to draw fresh blood from the neighbourhood of an inflamed part, never to remove blood already effused. The small end of the leech is the mouth end. To apply it, wash and dry the part thoroughly. Meanwhile let the leech be swimming about in a vessel of water. When ready, take up the leech between the wet folds of a piece of clean lint and apply it to the desired part. It may be kept there by inverting over it a wine-glass. If several must be applied at once this is a suitable way of doing it. If the leech delays to bite, touch the part with a drop of sugar and water or milk. When the leech has withdrawn all it can, which usually occupies twenty minutes or more, it will drop off. When it does so put it into a vessel of water, a wide-mouthed bottle, for example, and cover the mouth very securely by a piece of cloth firmly tied below the edge. If a paper cover be used prick a few pin-holes in it. If the leech will not let go, do not pull it away, but sprinkle a few grains of salt upon it; it will relax its hold immediately. *Always be careful to dispose effectually of leeches that are no longer needed; and if leeches are being kept for any purpose, one cannot be too careful to have them securely fastened in their receptacle.* If they are carelessly tied up they will squirm their way out, and one cannot tell where ultimately they may wander, or what mischief they might succeed in doing. If it is desired to keep a leech bite bleeding, place a warm poultice over it; if it is desired to stop it, take a small piece of lint round the point of the finger and press firmly on the bite. Pressure with a thimble guarded by a piece of lint, will do. The bleeding will be stopped if pressure is kept up long enough. It is always proper to place a leech on a spot which can easily be compressed against a bone to stop the bleeding. For instance, a leech ought never to be put on the neck, nor over a vein. Glass tubes are provided to aid in the application of leeches.

Suppositories are small cones, like miniature sugar-loaves, made with cocoa butter and containing some active drug like morphia, belladonna, &c., for passing up into the bowel. They are quite easily introduced, specially if touched with oil. **Pessaries** are similar preparations, but larger, for the vaginal passage.

A FEW RECIPES FOR SICK-ROOM COOKERY.

1. Beef-tea. See p. 627.

2. Peptonized Beef-tea. See p. 847.

3. Peptonized Milk, Sago, &c. See p. 847.

4. Beef-tea with Oatmeal.

Mix two table-spoonfuls of oatmeal very smoothly with two spoonfuls of cold water, add a pint of strong beef-tea. Boil together for 5 or 6 minutes, stirring well all the time. Strain through a sieve and serve (*Ringer*). Arrowroot or corn-flour may be used instead of oatmeal, and needs no straining.

5. Beef-tea Pudding.

Stew 1 ounce of well-washed sago in half a pint of water till it is reduced to a half. Beat up one egg in a tea-cupful of cream, and slowly add this to the sago with constant stirring. Then add with constant stirring 4 tea-cupfuls of strong hot beef-tea.

6. Vegetable Soup.

Take two large peeled potatoes, an onion, and crumb up ½ lb. stale bread; put them into a quart of water and boil down to a pint. Strain and add a few sprigs of parsley and a small quantity of salt, and, if desired, pepper. Cover and allow to get cold. It may be warmed for use. When animal food is not allowed, this is a good article of diet (*Wood*).

7. Veal Jelly.

1 lb. lean veal, 1 breakfast-cupful of water, a piece of turnip the size of an egg, a pinch of salt. Slice the veal very thinly, and put it in a jar alternately with slices of the turnip cut very thinly, to which add the small pinch of salt and the water. Cover the jar very tightly with a paper, and put it in a saucepan of boiling water, coming more than half-way up the jar. Boil continuously for 4 hours. Then strain and use.

8. Bread Jelly.

Take the crumb of a loaf, break it up, pour boiling water over it, and leave it to soak for 3 hours. Then strain off the water and add fresh. Place the mixture on the fire and let it boil till it is perfectly smooth. Take it out, press out the water, flavour to taste, press it into a mould, and turn it out when it is required for use.

9. Port Wine Jelly.

To a pint of port wine in a jar add 1 ounce of the best gum arabic and 1 ounce fine gelatine.

and a grated nutmeg. Let them stand an hour. Then put the jar into a sauce-pan over a slow fire till all is thoroughly dissolved. Add sugar according to taste. Strain it into a flat dish, and when it is nearly cold cut into squares.

10. Water Panada.

Put a pint of cold water and two slices of dry bread into a stew-pan and boil for three quarters of an hour, stirring occasionally. Add salt, stir in the yolk of an egg, flavour to taste, and serve.

11. Milk Panada.

To a tea-cupful of stale bread-crumbs add boiling water sufficient to cover them, and when they are soft mix thoroughly. Put the mixture into a pint of milk, boil and stir till it thickens. Sweeten, or add salt, and flavour according to taste.

12. Egg Nogg.

Best French brandy, 4 ounces; cinnamon water, 4 ounces; yolks of two eggs; sugar, ½ ounce. Rub the sugar and egg yolks together, then add the rest; or,

13.

Beat a whole egg for 5 minutes, adding a small quantity of sifted sugar and a cup of milk, warm or cold. To this may be added a small quantity of wine or brandy and a grated nutmeg. If milk is not desired, beat the egg and sugar together and add the wine or brandy.

14. Brandy and Egg Mixture. See Prescriptions, No. 63.

15. Oatmeal Gruel.

Put into a small basin a table-spoonful of Scotch oatmeal. After wetting it with a very little cold water, pour over it a pint of boiling water or milk, stirring all the time. Stir it for a few minutes, then allow it to settle one minute. Pour carefully into a clean sauce-pan all the liquid, and stir over the fire till it boils. Let it boil for 10 minutes, when it is ready for use. It may be sweetened with honey, sugar, or treacle; or it may be flavoured with salt and a small piece of butter. It should be taken very hot (*Mrs. Black*).—Or,

16.

Use the same quantity of oatmeal, a little more than half the quantity of boiling water, and salt to taste, and boil as directed. Then add half a pint of butter-milk, and a little bit of butter.

17. Black Currant Jam Water.

Two table-spoonfuls of jam are added to 4 tea-cupfuls of water in a sauce-pan and allowed to simmer for half an hour, and then strained. It may be drunk hot in cases of feverish sore throat, or after it has become cool for thirst.

18. Barley Water.

Wash 1 table-spoonful of barley, put it into a jug with the rind of one lemon and a tea-spoonful of sugar. Pour over it 3 tea-cupfuls of boiling water; then cover the jug and let it stand till cold. Pour off the liquid for use.

19. White Wine Whey.

To a breakfast-cupful of boiling milk add one or two wine-glassfuls of sherry. Strain through a fine sieve and sweeten with sifted sugar.

20. Oatmeal Water.

Put a large table-spoonful of oatmeal into a jug, and pour over it a pint of cold water. Stir well, allow the meal to settle. Then strain and use the water, flavoured if desired.

PRESCRIPTIONS.

The accompanying prescriptions are arranged in divisions in the following order:—

I. Tonic mixtures.
II. Purgative „
III. Diarrhœa „
IV. Fever „
V. Stimulant „
VI. Soothing „
VII. Cough „
VIII. Gargles, Mouth Washes, Tooth Powders.
IX. Liniments, Lotions, and Washes, including Eye Washes and Ointments, and Hair Washes.

In the prescriptions the weights and measures used are as follows:—

1 fluid ounce = 8 fluid drachms.
1 fluid drachm = 60 drops.
1 tea-spoonful means 1 fluid drachm or 60 drops.
1 dessert „ „ 2 „ drachms or 120 „
1 table-spoonful means 2 dessert-spoonfuls or 4 tea-spoonfuls, and is equal to ½ fluid ounce.
The measure by weight is 60 grains 1 drachm, 8 drachms 1 ounce.

I.—TONICS.

Simple Acid Tonics.

1. *Dilute Hydrochloric Acid,*
Dilute Sulphuric Acid,
Dilute Nitro-Hydrochloric Acid, or
Aromatic Sulphuric Acid.

Any of these acids is useful as a general tonic in debility, in some forms of indigestion (see pp. 158 and 179), in looseness of bowels from catarrh (p. 179), in liver complaints (see p. 195), and similar disorders.

The dose is the same for each acid, namely, from 10 to 20 drops in a wine-glassful of water, taken after food. For a child 5 drops are sufficient. The aromatic sulphuric acid in water relieves thirst and checks profuse perspiration.

Acid Tonic with Quinine.

2. *Aromatic Sulphuric Acid,* 6 *fluid drachms.*
Sulphate of Quinine, . 24 *grains.*
Syrup of Orange, . . 2 *ounces.*
Water, ... *up to* 8 „

Dose: One table-spoonful in the same quantity of water thrice daily.

Useful in depressing disorders, see *Carbuncle* (p. 315).

Acid Tonic with Bark (Peruvian).

3. *Dilute Sulphuric Acid,* . . . . ½ *ounce.*
Compound Tincture of Cinchona, 1½ *ounces.*
Syrup of Orange, ... 2 „
Infusion of Yellow Cinchona, up to 8 „

Dose: One table-spoonful in water twice or thrice daily with meals.

As a general tonic and in depressed states.

Bark as a Tonic.

4. Any of the *Cinchona Barks* in powder may be used alone as a tonic in doses of 15 grains, or the tincture in doses of ½ to 1 tea-spoonful in water. They are useful in checking looseness of bowels, sweating, &c.

5. *Tincture of Red Cinchona Bark* has a repute in allaying the craving for spirit of chronic drunkards (see p. 105).

Bitter Tonic.

6. *Tincture of Nux Vomica,* . 8 *drops.*
Infusion of Chiretta, . *up to* 4 *ounces.*

Dose: A fourth part taken before meals.

Useful as an aid in slow digestion.

Bitter Tonic with Ammonia or Soda.

7. *Aromatic Spirit of Ammonia,* . . ½ *ounce.*
Compound Tincture of Cardamoms, 1 „
Infusion of Calumba, . . *up to* 8 *ounces.*

Dose: A table-spoonful before meals.

8. Instead of the Aromatic Spirit of Ammonia *Bicarbonate of Soda or Potash* (80 *grains*) may be dissolved with the bitters.

Bitter Tonic with Acid.

9. *Dilute Hydrochloric Acid,* . . 3 *drachms.*
Tincture of Nux Vomica, . . 40 *drops.*
Infusion of Chiretta, . . *up to* 4 *ounces.*

Dose: A dessert-spoonful in a like quantity of water to be taken after meals.

These bitter tonics are all useful to rouse the stomach and aid digestion (see p. 179). The simple bitters, as well as those with ammonia, soda, or potash, should be taken immediately before meals, that with acid immediately after meals. The last is specially useful where indigestion is accompanied by sluggish and loaded liver (see p. 195), and in flatulent indigestion (see p. 181).

Simple Iron Tonics.

The simplest iron tonic is—

10. *Tincture of Steel.*

Dose: 10 drops in water five times daily.

It is useful in erysipelas (see p. 315), and in most conditions of ill-health dependent upon a poor quality of blood (see Anæmia, p. 234).

11. *Dialysed Iron.*

Dose: 5 to 15 drops in water four or five times daily.

Useful in weak conditions of body, rickets (see p. 30), and bloodlessness (anæmia, see p. 235). It is less binding to the bowels than tincture of steel.

Iron and Quinine.

12. *Tincture of Steel,* . . . . $2\frac{1}{2}$ *drachms.*
Sulphate of Quinine, . . . 48 *grains.*
Syrup of Orange, ... $1\frac{1}{2}$ *ounces.*
Water,[1] . . . . . *up to* 4 „

Dose: A tea-spoonful in half a wine-glassful of water some time after food.

A good general tonic.

Iron, Quinine, and Strychnine.

13. *Citrate of Iron and Quinine,* . 90 *grains.*
Liquor Strychniæ, ... 90 *drops.*
Water, ... *up to* 4 *ounces.*

Dose: A tea-spoonful in a table-spoonful of water thrice daily, an hour or more after food.

A good general and nerve tonic.

14. *Easton's Syrup* consists of a combination of iron, quinine, and strychnine, and is a useful tonic for debility.

The dose is a tea-spoonful in water.

The combinations with strychnine are useful in weak conditions, accompanied by nervous exhaustion and debility.

Iron and Arsenic.

15. *Citrate of Iron and Quinine,* $2\frac{1}{2}$ *drachms.*
Liquor Arsenicalis, . . . 60 *drops.*
Tincture of Quinine, . . . 2 *ounces.*
Syrup of Orange, ... 2 „
Water, ... *up to* 8 „

Dose: A dessert-spoonful in two-thirds of a wine-glassful of water.

Useful in skin diseases (see p. 317), in impoverished conditions of the blood, see *Anæmia* (p. 235), and purpura (p. 237), in nerve affections, such as neuralgia (see p. 127).

Iron and arsenic are also extensively used in various diseases of women (see p. 509).

[1] Chloroform water instead of plain water would make this mixture more palatable.

Iron and Phosphorus.

16. *Reduced Iron,* . . . . 50 *grains.*
Sulphate of Quinine, ... 25 „
Phosphorus, ... $\frac{1}{4}$ *grain.*
Extract of Nux Vomica, . . . 13 *grains.*
Extract of Gentian, ... 25 „

To be made into a pill mass and divided into 25 pills.

Dose: One pill thrice daily *on a full stomach.*

This is an exceedingly useful pill in most cases of nervous depression, nervous headache, neuralgia (p. 127), and nervous irritability, the result of exhaustion. On p. 113 the prescription for a stronger pill is given.

Iodide of Iron.

17. *Syrup of the Iodide of Iron* is the form in which this combination of drugs is usually ordered.

Dose: One half to one tea-spoonful in water three or four times daily. For very young children a quarter of a tea-spoonful is sufficient.

In all cases of illness associated with scrofula (p. 431) this is one of the best remedies. In scrofulous inflammation of bone (p. 26), scrofulous diseases of glands (p. 209), &c., it is very useful.

18. *Compound Syrup of the Phosphate of Iron* (Parrish's Syrup or Chemical Food), and

19. *Compound Syrup of the Hypophosphites,* are now both very extensively used for the treatment of cases of general debility, specially in the young. Various forms of No. 19 are now in the market, all more or less useful.

The dose in the case of any of these is from a third to one tea-spoonful (according to age) in water thrice daily a short time after food.

Iron and Chlorate of Potash.

20. *Chlorate of Potash,* . . . . 90 *grains.*
Dialysed Iron, ... $\frac{1}{2}$ *ounce.*
Syrup of Orange, ... $1\frac{1}{2}$ *ounces.*
Water, ... *to* 4 „

Dose: A tea-spoonful in water four times daily.

Useful for those subject to relaxed throat (p. 157) or to attacks of inflamed tonsils.

II.—PURGATIVE MIXTURES AND PILLS.

Castor-oil.

21. Castor-oil may be taken as a safe purgative, at any time, in doses of from 2 to 3 tea-spoonfuls. Its taste may be entirely disguised by mixing it with a tea-cupful of beef-tea well peppered and salted. Or it may be mixed with half a tea-cupful of boiling milk. The boiling milk is gradually added in small quantities, being thoroughly stirred with the oil, till the oil is thoroughly incorporated with the milk, no large globules of oil being visible. *The milk must be boiling, and must be slowly added with constant stirring.*

Castor-oil and Laudanum.

22. *Castor-oil,* . . . . . 1 *ounce.*
Tincture of Rhubarb, . . 1 *tea-spoonful.*
Laudanum, ... 15 *drops.*
Syrup of Orange, . . . 1 *tea-spoonful.*
Cinnamon Water, . . . ½ *ounce.*

Mix. The addition of two tea-spoonfuls of mucilage of gum arabic or gum tragacanth will permit of an emulsion being formed.

This mixture is very useful in looseness and irritability of bowels, due to irritating material in the bowel. After the opening effect is produced, clearing out the bowel, the soothing effect of the laudanum and the astringent action of the rhubarb come into play arresting further action.

This is only for adults.

Epsom Salts.

23. *Epsom Salts,* . . . . . . ½ *ounce.*
Acid Infusion of Roses, . . 2 *ounces.*

Add to any desired quantity of water. To be taken early in the morning.

This may be used for any feverish complaint, such as inflamed sore throat (p. 155) or feverish cold (p. 158) of the stomach.

Black Draught.

24. *Epsom Salts,* . . . . . . 4 *ounces.*
Rochelle Salts, ... 2 „
Essence of Senna, ... 7 „
Aromatic Spirit of Ammonia, . 1 *ounce.*
Compound Tincture of Cardamoms, ... 1 „
Water, ... 16 *ounces.*

Take three or four table-spoonfuls in water early in the morning.

This is found to be a valuable purgative after a drinking bout, as a relief to the headache and stomach and liver disorder.

Seidlitz Powder.

25. *Rochelle Salts,* . . . . . 120 *grains.*
Bicarbonate of Soda, . . 40 „

Dissolve in a tumblerful of water and then add 37 grains of tartaric or citric acid. Stir and drink during effervescence.

This is taken in the morning as a mildly opening draught.

Fruit Saline.

26. *Tartaric Acid,* . . . . . 9 *ounces.*
Bicarbonate of Soda, . . . 10 „
Chlorate of Potash, . . . ¼ *ounce.*
Epsom Salts, ... 3 *drachms.*
Powdered Sugar, ... 3 *ounces.*

Or,

27. *Tartaric Acid,* . . . . . 13 *ounces.*
Bicarbonate of Soda, . . . 14 „
Chlorate of Potash, . . . ½ *ounce.*
Epsom Salts, ... 2 *ounces.*
Sugar, ... 1½ „

Mix. Note each ingredient should be well dried before mixing.

These salines are useful as a mild opening medicine to be taken in early morning, 2 or 3 tea-spoonfuls in ½ tumblerful of water. In feverish states they may be safely taken by any one.

Lamplough's Pyretic Saline.

28. *Tartaric Acid,* . . . . . 9 *ounces.*
Bicarbonate of Soda, . . . 10½ „
Chlorate of Potash, . . . 3 „

Mix. Use as above.

Calomel and Jalap.

29. *Calomel,* . . . . 5 *grains.*
Powder of Jalap, ... 15 „

Mix. Give in a little water; three hours later give the following draught:—

30. *Epsom Salts,* . . . ¼ *ounce.*
Manna, ... 60 *grains.*
Tincture of Jalap, . 2 *tea-spoonfuls.*
Cinnamon Water, . 2½ *table-spoonfuls.*

This is the prescription for threatened affections of the head (see p. 101, inflammation of the membranes of the brain), and to reduce the stage of excitement that follows injuries to the head (see p. 104). It is also useful to relieve a loaded liver (p. 197, 198), and as an active purgative at the beginning of many acute diseases, inflammation of the kidney or lung for example.

Calomel and Rhubarb for Children's Powders.

31. *Calomel*, ... ½ *to* 2 *grains.*
Powdered Rhubarb, . . . 3 *to* 8 „
Aromatic Powder, ... 4 „

This may be given to children in cases of thread-worm (p. 174), in feverishness accompanying teething, and in head affections in children. For instance, if a child has had a fall or blow on the head it is well to give such a powder by way of preventive of nervous excitement following. The actual dose depends upon the age. The amount named would be suitable for children between 1 and 5 years, the smaller dose noted for the younger child.

Grey Powder and Soda for Children.

32. *Grey Powder*, ... ½ *to* 3 *grains.*
Carbonate of Soda, ... 6 „
Sugar of Milk, ... 3 „

This is suitable for disordered states of the bowels in children where there is looseness of bowels, and the motions are curdy white, with pieces of undigested milk throughout. One morning and evening may be given.

In regard to grey powder the general rule for what are called "Cooling Powders" is, for a child between 1 and 6 months, ½ grain grey powder, 6 grains of the soda; for a child between 6 and 12 months, 1 grain grey powder, 6 of soda; between 1 and 3 years, 1½ grains grey powder, 6 soda; and between 4 and 8 years, 3 grains of grey powder with 6 of soda.

Jalap and Senna.

33. *Compound Jalap Powder*, 30 *to* 60 *grains.*
Syrup of Senna, . . . 1 *tea-spoonful.*
Camphor Water, . . . 4 *table-spoonfuls.*

Mix and give in water early every morning. This promotes a watery discharge from the bowel, and is useful in dropsy consequent upon liver disorder (see p. 435).

Aloes.

34. *Tincture* (*or Wine of Aloes*), 1 *tea-spoonful.*
Infusion of Senna, . . 2 *table-spoonfuls.*
Epsom Salts, ... ¼ *ounce.*

Mix and take in water in early morning.

The aloes acts principally on the large bowel, and is specially useful in habitual costiveness, with hard dry motions. The following is an excellent pill, containing the active principle of aloes, namely aloin, in cases of constant constipation, specially when it is due to want of sufficiently active exercise in the open air.

35. *Aloin*, ... *gr.* ⅕
Extract Belladonna, ... *gr.* ⅙
Extract of Nux Vomica, . . . *gr.* ½
Hard Soap, ... *gr.* ½

Make into a pill. Let one such pill be taken either at bed-time, in which case it should act after breakfast next morning, or in early morning, in which case it should act after dinner.

Podophyllin.

36. *Resin of Podophyllin*, ... *gr.* ⅓
Extract of Nux Vomica, ... *gr.* ½
Extract of Hyoscyamus, ... *gr.* 1
Hard Soap, ... *gr.* ½

Make one pill. Take one such pill before breakfast each morning. This is a very suitable pill for sluggish liver and the costiveness that usually accompanies it (p. 195), and it relieves at the same time the indigestion and headache that are usually produced by it.

Rhubarb and Magnesia.

37. *Carbonate of Magnesia*, . . . 10 *grains.*
Powdered Rhubarb, ... 5 „
Aromatic Powder, ... 5 „

This is a suitable powder for feverish conditions in children and for disordered states of stomach and bowel (p. 460).

Another way of administering the same remedies to infants is as follows:—

38. *Powdered Rhubarb*, . . . 15 *grains.*
Carbonate of Magnesia, . 60 „
Dill Water, ... 3 *table-spoonfuls.*

Give of this mixture a tea-spoonful every two hours till the bowels are freely opened.

Mixture for Gout.

39. *Sublimed Sulphur*, ... 2 *ounces.*
Cream of Tartar, ... 1 *ounce.*
Powdered Rhubarb, ... ¼ „
Resin of Guaiac Powder, . . 1 *drachm.*
Honey, ... 1 *pound.*
One Nutmeg reduced to powder.

Mix thoroughly.

This is a mixture formerly in much repute for gout and chronic rheumatism, and was well known under the name of the "Chelsea Pensioner." The dose is 2 tea-spoonfuls night and morning till the whole is consumed.

III.—DIARRHŒA MIXTURES.

The few mixtures for diarrhœa that will be mentioned here are not to be given at random. Let the reader refer to Diarrhœa (p. 184), and to the paragraphs on Remedies

for Diarrhœa (p. 866). It is possible that by acting on the instructions given there, the looseness of bowels may be checked without the use of any astringent remedies, which by their binding effect tend to cause costiveness afterwards. The following prescriptions are to be resorted to only if simpler means fail, or if pain, griping, and excessive discharge make the case urgent:—

Bismuth and Ipecacuanha.

40. *Carbonate of Bismuth*, . . . 10 *grains*.
Powder of Ipecacuanha, . . 5 „

Mix. Give one powder every two or three hours, till the diarrhœa is checked.

Bismuth, Ipecacuanha, and Opium.

41. *Carbonate of Bismuth*, . . . 10 *grains*.
Dover's Powder (*Compound Ipecacuanha Powder, which contains* 1 *grain opium in* 10 *of powder*), ... 5 „

Mix. Give one powder every four hours if necessary.

Catechu and Chalk Mixture.

42. *Tincture of Catechu*, $\frac{1}{2}$ *ounce* (1 *table-spoonful*).
Oil of Peppermint, . . 6 *drops*.
Aromatic Chalk Powder, 90 *grains*.
Chalk Mixture, . . *to* 8 *ounces*.

Give an eighth part after each loose motion. If this treatment fail, add 8 drops of laudanum to each dose.

It is well to make certain, before giving this mixture, that no irritating material is lodging in the bowel by administering a table-spoonful of castor-oil three or four hours before the mixture is begun, if the case is not too urgent.

43. Ipecacuanha Powder used in large doses, as detailed on p. 852, is given in the Tropics for dysentery.

44. *Liquid Extract of Bael Fruit*, ... 1–2 *tea-spoonfuls*.
Syrup of Red Gum, . . 1 *tea-spoonful*.
Water, ... 1 „

Mix. This is recommended for chronic dysentery (p. 186) given three or four times a day.

Diarrhœa Mixtures for Children.

45. *Carbonate of Bismuth*, . 80 *grains*.
Ipecacuanha Wine, . . 80 *drops*.
Aromatic Spirit of Ammonia, ... $1\frac{1}{2}$ *tea-spoonfuls*.
Simple Syrup, . . . $\frac{1}{2}$ *ounce* (1 *table-spoonful*).
Mucilage of Gum Arabic, $\frac{1}{2}$ *ounce*.
Water, ... *to* 2 *ounces*.

Mix. Give a tea-spoonful every three hours to a child 1 year old, and half the quantity to a 6-months'-old child. If it were absolutely necessary, one drop of laudanum might be added to the dose for the year-old child. But this should not be done unless medical advice is not within reach.

46. *Aromatic Powder of Chalk and Opium*, ... 20 *grains*.
Carbonate of Bismuth, . . . 60 „

Mix and divide into 10 powders. One of these could be given every third hour to a child 1 year old. Note that in aromatic chalk and opium powder there is $\frac{1}{2}$ grain of opium in the 20 grains of the powder, so that in each of the 10 powders there would be $\frac{1}{20}$th grain of opium.

Diarrhœa with Blood in the Motions.

47. The *Catechu and Chalk* mixture (No. 42) may be used with the addition to each dose of 5 drops tincture of witch-hazel or *Hamamelis virginica* (p. 835), or 1 tea-spoonful of the American preparation, Pond's extract, or the same quantity of the English preparation, hazeline. The following may also be taken:—

48. *Tincture of Steel* (*steel drops*), ... 15 *drops*.
Dilute Hydrochloric Acid, 10 „
Orange Flower Water, 3 *table-spoonfuls*.

Mix and take the whole quantity in water, to be repeated every 6 hours.

The same may be used in bleeding from the stomach. See also p. 835.

IV.—FEVER MIXTURES.

Quinine.

49. *Quinine* is often the best drug to use in cases where there is considerable fever. It is sometimes best given alone, simply stirred in a wine-glassful of cold water.

Dose: 3 to 5 grains every 4 or 6 hours.

In cases where the fever heat is very great, such as cases of acute inflammation of glands (p. 207), or of blood poisoning (p. 236), or in cases of ague (p. 427), a large dose should be given at once, namely:

10 grains, and it may be repeated in six hours.

Salicine.

50. *Salicine* or Salicylate of Soda is one of the most quickly acting remedies in rheumatic fever (p. 430).

Dose: 20 grains in water every two hours

till the pains are relieved. Thereafter four doses daily for several successive days.

Quinine and Salicine.

51. *Quinine*, ... 5 *grains*.
Salicine, ... 20 „

This makes one powder to be given all at once.

This is a combination useful in some feverish conditions. It is specially useful in neuralgic affections (p. 127).

52. *Antipyrin* and its use in fever is sufficiently detailed on p. 821.

Dover's Powder.

53. *Dover's Powder* is useful at the very outset of a feverish cold (see *Catarrh*, p. 154, and *Cold in the Stomach*, p. 158), inflammation of the bowels (p. 162), and child-bed fever (p. 518).

Every 10 grains of the powder consist of
Powdered Opium, ... 1 *grain*.
Powdered Ipecacuanha, . . . 1 „
Sulphate of Potash, ... 8 *grains*.

Dose: 10 grains given in water.
It must never be given to children.

Acetate of Ammonia.

54. *Liquor Acetate of Ammonia*, . . 5 *ounces*.
Simple Syrup, ... $1\frac{1}{2}$ „
Water, ... *to* 8 „

Dose: From a tea-spoonful (for children) to a table-spoonful (for adults) in water every three hours.

Used in all feverish diseases, especially in those accompanied by skin eruption. It promotes sweating and this reduces the fever.

Ammonia and Ether.

55. *Liquor Acetate of Ammonia*, . 3 *ounces*.
Spirit of Nitrous Ether, . . . 1 *ounce*.
Simple Syrup, ... 1 „
Water, ... *to* 6 *ounces*.

Dose: From a tea-spoonful to a table-spoonful (according to age) in water every three hours.

Useful in the beginning of most fevers.

Another prescription for Ammonia and Ether is given on p. 402.

V.—STIMULANT MIXTURES.

Ammonia.

56. *Carbonate of Ammonia*, . . . 80 *grains*.
Syrup of Ginger, ... 1 *ounce*.
Water, ... *to* 4 *ounces*.

Dose: Two tea-spoonfuls in water every four hours.

Useful in faintness, wind on the stomach (p. 243), in nervous and hysterical persons, and as a general stimulant.

Ammonia and Ether.

57. *Carbonate of Ammonia*, . . 120 *grains*.
Chloric Ether, ... 3 *drachms*.
Infusion of Senega, . . . 6 *ounces*.

Dose: A dessert-spoonful in a wine-glassful of water every three hours.

A valuable stimulant in chronic bronchitis (p. 271), and in exhaustion in cases of inflammation of the lungs (p. 275), and other weakening diseases, such as typhoid fever.

58. *Aromatic Spirit of Ammonia*, $1\frac{1}{2}$ *ounces*.
Chloric Ether, ... $2\frac{1}{2}$ *drachms*.
Syrup of Ginger, ... 1 *ounce*.
Water, ... *to* 4 *ounces*.

Dose: A dessert-spoonful in a wine-glassful of water as required.

May be used for faintness, and giddiness in nervous people troubled with wind on the stomach (p. 181). The same is useful in hiccup (p. 182) and palpitation, and is aided by the addition to each dose of 10 drops of spirit of camphor, or the mixture may be made up to 4 ounces with camphor water instead of simple water. With the addition of camphor the mixture is useful in looseness of bowels (p. 184), and in tea-spoonful doses might be given to children.

59. *Aromatic Spirit of Ammonia*, $\frac{1}{2}$ *tea-spoonful*.
Carbonate of Magnesia, . 20 *grains*.
Spirit of Chloroform, . . $\frac{1}{2}$ *tea-spoonful*.
Peppermint Water, . *to* $1\frac{1}{2}$ *ounces*.

Make a draught with water. To be taken all at once for colic, hysterical faintness, flatulence, &c.

60. Stimulant Mixture for children with wind on the stomach and colicky pain.

Carbonate of Magnesia, . . 60 *grains*.
Sugar of Aniseed, ... 60 „
Aromatic Spirit of Ammonia, 30 *drops*.
Compound Tincture of Cardamoms, ... 2 *drachms*.
Dill Water, ... *to* 2 *ounces*.

Mix. A tea-spoonful for a dose, repeated as required.

Caffein and Guarana—Nerve Stimulants.

61. The active principle of coffee—caffein—and the active principle of the Brazilian cocoa—guarana—are useful nervous stimulants in certain cases. They are frequently used in nervous headache.

The caffein is given in doses of 1 to 5 grains in water, or may be obtained as effervescing citrate of caffein, of which a tea-spoonful in half a tumbler of water is the dose, and it may be frequently repeated.

The dose of guarana is 15 to 30 grains given in water, and repeated for a time every two hours if necessary.

Ether and Brandy.

62. *Chloric Ether,* . . . . 3 *drachms.*
French Brandy, ... $1\frac{1}{2}$ *ounces.*
Infusion of Yellow Cinchona, to 8 „

Dose: Two table-spoonfuls to be given occasionally.

In convalescence from acute diseases or in low fevers.

Brandy and Egg Mixture.

63. Beat up an egg till it froths, add a lump of sugar and two table-spoonfuls of water, mix well; pour in half a small wine-glassful of brandy, or, instead, one wine-glassful of sherry, and administer before it gets flat.

Useful in convalescence from exhausting diseases.

Brandy and Milk.

64. Pour a table-spoonful of brandy or a wine-glassful of sherry into a cup, add a little powdered sugar and very little nutmeg to taste. Warm a breakfast-cupful of new milk and pour it into a jug with a spout. Pour the milk from a height into the cup containing the brandy or wine. The milk must not be boiled.

Beef and Iron Wine.

65. Several chemists now make a preparation of beef, wine, iron, or meat and malt wine, &c.

These are useful in weak states of health, and often very useful in exhausting diseases of children.

The Beef and Iron Wine of Burroughs Welcome & Co., and the Extract of Meat and Malt Wine of Coleman, are illustrations.

VI.—SEDATIVE (SOOTHING) MIXTURES.

66. *Bromide of Potassium* is one of the simplest and safest (if not used with unnecessary frequence) of soothing drugs.

Dose: For adults, ... 30 grains.
For young children, . . 5 „

It should be dissolved in sweetened water.

It is exceeding valuable in many nervous diseases, especially epilepsy (p. 123), inflammation of the brain (p. 100) and spinal cord (p. 117), child-crowing (p. 464), somnambulism (p. 116), and sometimes sick-headache and neuralgia.

67. *Belladonna* is also very serviceable in nervous diseases, especially spasmodic diseases, such as epilepsy (p. 123). It is one of the best remedies in whooping-cough (p. 416).

At the places referred to directions are given for the use of the drug.

68. *Extract of Belladonna,* . . . $\frac{1}{6}$ *grain.*
Extract of Hyoscyamus (*Henbane*), $1\frac{1}{2}$ *grains.*
Extract of Gentian, ... 1 *grain.*

To be made into one pill.

Dose: One pill, to be repeated twice or thrice within eight hours if required.

Useful in allaying irritation of bowels and bladder (p. 305).

69. *Extract of Indian Hemp* (*Cannabis Indica*), ... $1\frac{1}{2}$ *grains.*
Extract of Henbane, ... 6 „
Extract of Gentian, ... 6 „

Make into a pill mass and divide into six pills.

Dose: One pill repeated thrice or four times daily if necessary.

This is extremely soothing in sick-headache (p. 113), in various painful diseases of women (p. 510 and 504). It is also used for sleeplessness (p. 117). In such a case the dose should not be larger than $\frac{1}{4}$ grain of the Indian Hemp to begin with.

Opium or its chief active principle morphia is one of the most powerful of soothing remedies. One mixture containing it will, therefore, be given.

70. *Liquor Hydrochlorate of Morphia,* $\frac{1}{2}$ *ounce.*
Tincture of Hyoscyamus, . . 1 „
Syrup of Orange, ... 1 „
Water, ... *to* 4 *ounces.*

Dose: A dessert-spoonful in water, to be repeated in two or three hours, only if necessary.

This mixture is likely to relieve most painful affections of the stomach and bowels, many spasmodic diseases, spasmodic cough, &c. *It ought not to be given for cough when any defluxion is brought up by coughing, and it ought never to be given to children.*

VII.—COUGH MIXTURES.

A separate paragraph relating to cough mixtures is given here mainly to warn persons against the indiscriminate use of the ordinary mixtures. Cough is certain to exist wherever

there is phlegm or matter in the air-tubes, and is the natural method of expelling the offending material. To stop cough, in such cases, is certain to do harm by causing the material to remain and accumulate in the lungs or air-passages. In such cases the proper treatment is to give medicine which will aid the expulsion of the material, and thus relieve the cough. But, in the second place, the cough may be due to irritability of the air-passages without the presence of any material to be expelled. In such cases soothing drugs are needed. For further details see p. 284. The difference may be put by calling the first class of cases that of cough with spit and the second class that of dry cough.

For Cough with Spit.

71. *Ipecacuanha Wine* 5 to 40 drops, according to age, in a table-spoonful of water.

Useful in rendering the defluxion more fluid so that it is more readily expelled.

72. *Carbonate of Ammonia*, . . . 16 *grains*.
Ipecacuanha Wine, ... 80 *drops*.
Camphor Water, ... *to* 4 *ounces*.

A dessert-spoonful every two or three hours. Useful *for children* to aid the expulsion of matter from the air-tubes in bronchitis, whooping-cough, &c.

73. *Carbonate of Ammonia*, . . 40 *grains*.
Spirit of Ether, ... 2 *drachms*.
Tincture of Squill, ... 1½ „
Tincture of Camphor, . . . 2 „
Infusion of Senega, . . *to* 4 *ounces*.

Mix: Give one table-spoonful in water every four hours.

Useful for helping the cough in the bronchitis of *old people*.

For Dry Cough.

74. *Ipecacuanha Wine* may be used as directed for cough with spit. It often gives great relief when sprayed into the back of the throat by means of the spray producer (see Plate of Appliances for the Sick-room). A few drops of the wine added to some honey and water would make a soothing mixture for children, or liquorice juice might be employed for the same purpose.

75. A very useful cough mixture when the cough is the result of irritability of the air-passages will be found under Sedative (Soothing) Mixtures, No. 70. It should not be given to children.

No cough mixture containing laudanum, or other preparation of opium, such as paregoric elixir, or a drug like chlorodyne, should be given to children without a physician's orders.

VIII.—GARGLES AND MOUTH WASHES AND TOOTH POWDERS.

Borax Gargle.

76. *Borax*, ... ¼ *ounce*.
Tincture of Myrrh, ... 1 „
Water, ... *to* 8 *ounces*.

Mix. Gargle the mouth with a small quantity added to an equal quantity of lukewarm water twice daily in cases of ulcers about the mouth and throat (p. 149), or in relaxed sore throat and inflammation of tonsils (p. 155).

Borax and Glycerine.

77. *Borax*, ... ¼ *ounce*.
Glycerine, ... 1 „

Dissolve and apply with a brush in cases of ulcers and cracks of tongue, sore throat, &c. (p. 155).

Alum Gargle.

78. *Burnt Alum*, ... 80 *grains*.
Tincture of Myrrh, ... 1 *ounce*.
Water, ... *to* 7 *ounces*.

Mix. Apply this to the gums, mouth, throat, &c., in cases similar to above.

Alum and Catechu Gargle.

79. *Burnt Alum*, ... 90 *grains*.
Tincture of Catechu, . . . 1 *ounce*.
Tincture of Cayenne, . . 1 *tea-spoonful*.
Glycerine, ... 1 *ounce*.
Water, ... *to* 4 *ounces*.

Mix. This is a very useful gargle in cases of relaxed sore throat, in which case diluted with an equal quantity of warm water it may be used several times a day. It may also be applied, full strength, by means of a camel's-hair pencil at the very onset of an inflamed sore throat.

Tannic Acid Gargle.

80. *Tannic Acid*, ... 90 *grains*.
Tincture of Myrrh, ... ½ *ounce*.
Glycerine, ... 1 „
Water, ... *to* 4 *ounces*.

Mix. In cases of relaxed sore throat, ulceration of mouth, loosening of teeth, spongy gums, this is useful diluted with three times the quantity of warm water, or applied, half strength, by a camel's-hair pencil.

Carbolic Acid and Myrrh Mouth Wash.

81. *Carbolic Acid* (*Calvert's, No.* 2), ½ *ounce*.
Tincture of Myrrh and Borax, . ½ „
Glycerine, ... 2 *ounces*.
Water, ... 1 *ounce*.

Mix. About half a tea-spoonful of the mixture in a third of a tumblerful of warm water makes a most soothing and pleasant mouth wash. It is valuable for decaying teeth and spongy gums, removes offensive odour from the breath, and is effective in removing the smell of smoke from the breath.

Chlorate of Potash Mouth Wash.

82. *Chlorate of Potash,* . . . . ¼ *ounce.*
Tincture of Myrrh, ... ½ „
Glycerine, ... 1 „
Water, ... *to* 4 *ounces.*

Mix. This diluted with three or four parts of water may be used for sore throat, as a gargle, ulcerated mouth, &c.

Iron and Glycerine Gargle.

83. *Tincture of Steel,* . . . . . 1 *ounce.*
Glycerine, ... 1 „
Rose Water, ... 1½ *ounces.*
Water, ... *to* 4 „

Mix. Diluted with equal parts of water this may be used as a gargle for sore throat, or applied full strength by a camel's-hair pencil, or diluted with three or four parts of water it may be sprayed into the throat with a spray-producer for hoarseness.

Antacid and Astringent Tooth Powder.

84. *Precepitated Chalk,* . . . . 5 *ounces.*
Magnesia, ... 1½ „
Orris Root Powder, ... ½ *ounce.*
Sugar, ... ½ „
Tannic Acid, ... 30 *grains.*
Oak Bark in Powder, . . . 5 „
Powdered Hard Soap, . . . ¼ *ounce.*
Otto of Roses, ... 10 *drops.*
Oil of Lemon, ... 2 „

Mix.

Camphorated Chalk Tooth Powder.

85. *Camphor,* . . . . 1½ *ounces.*
Orris Root Powder, ... ½ *ounce.*
Precipitated Chalk, ... ½ *lb.*

Mix.

Antiseptic Tooth Powder.

86. *Powdered Castile Soap,* . . . 60 *grains.*
Precipitated Chalk, ... 2 *ounces.*
Eucalyptus Oil, ... 60 *drops.*
Carbolic Acid, ... 30 „

Mix thoroughly.

IX.—LINIMENTS, LOTIONS, AND WASHES.

Camphor Liniment.

87. *Camphor,* . . . . 1 *ounce.*
Olive or Cotton-seed Oil, . . . 4 *ounces.*

Crush the camphor and set it aside in the oil till it is dissolved.

Soap Liniment (Opodeldoc).

88. *Hard Soap,* . . . . 2½ *ounces.*
Camphor, ... 1¼ „
Oil of Rosemary, . . . 3 *fluid drachms.*
Rectified Spirit, . . . 18 *fluid ounces.*
Water, ... 2 „ „

Crush the soap and camphor and mix with the spirit and water, finally add the oil of rosemary.

Soap and Opium Liniment.

89. *Liniment of Soap,* . . } *of each* 1 *ounce.*
Tincture of Opium, . . }
(*Laudanum*). }

This is also frequently called opodeldoc. It is useful as a stimulating liniment for sprains, bruises, stiff joints, &c., *after all pain has ceased.* Sprinkled on flannel and applied to the throat it is useful in sore throat, hoarseness, and for the relief of cough. For sprains 1 tea-spoonful tincture of arnica may be added.

Ammonia and Camphor Liniment.

90. *Ammonia Water* (*Spirit of Hartshorn*), ... 1 *tea-spoonful.*
Liniment of Camphor, . . 1 *ounce.*

The above liniment is useful as a stimulant, for friction to the chest, stiff joints, rheumatic joints, &c.

Turpentine Liniment.

91. *Oil of Turpentine,* . . . . . 4 *ounces.*
Camphor, ... ¼ *ounce.*
Soft Soap, ... ½ „

Mix. This is employed as a stimulating liniment in cases mentioned under No. 90, and 3 ounces of it mixed with 5 of camphor liniment are used as a liniment for the chest in cases of chronic bronchitis, pain in the chest, and for sore-throat, hoarseness, &c.

Chilblain Liniment (Wardrop's).

92. *Tincture of Cantharides* (*Spanish-fly*), ... 3 *drachms.*
Soap Liniment, ... 9 „

Soothing Liniment.

93. *Liniment of Aconite*, . .
Liniment of Belladonna, } *of each* 1 *ounce.*
Liniment of Chloroform,

Mix. This is a very soothing mixture for rubbing on painful joints, rheumatic joints, for neuralgia, for pain in the back or side. (See p. 919.)

The liniments of aconite and belladonna are made by taking 20 ounces of the aconite or belladonna root, bruising and rubbing it into a coarse powder, and letting it steep for several days in rectified spirit, during which the mixture is frequently shaken up. Then the liquid portion is drained off, and the refuse washed with spirit. The total quantity obtained should be 20 fluid ounces. Finally an ounce of camphor is added.

The liniment of chloroform is made with two fluid ounces of chloroform, and two of liniment of camphor (No. 87).

Liniment of Lime (Carron-oil).

94. *Lime Water*, ... 1 *ounce.*
Olive, Linseed, or Cotton-seed Oil, 1 „

Mix. This is a most soothing application to burns (p. 999).

The lime-water is made with 1 ounce slaked lime, and 80 ounces (4 pints or ½ gallon) distilled water. Keep it in a stoppered bottle, and draw off the clear solution as required. The lime is slaked as follows: take 1 ounce fresh lime, add 1 fluid ounce boiling water and then 30 ounces cold water, and stir occasionally for half an hour. Allow it to stand an hour, carefully pour off the water. The white deposit remaining is the slaked lime. Lime-water may be straightway made from it by adding 30 ounces distilled water, stirring the mixture well for a time, then allowing the coarser particles to settle, and pouring off the watery portion into a stoppered bottle, where it stands till clear. The clear water is then used as required.

Lotions for Wounds.

95. These have been sufficiently indicated on p. 917 and p. 971.

Eye Lotions.

Chamomile-tea Wash.

96. *Chamomile Flowers*, . ½ *ounce.*
Boiling Water, . . . 10 *ounces* (½ *pint*).

Infuse for half an hour and strain.

This is a very mild eye wash. It may be diluted with lukewarm water for use. If a stronger solution is required, as when the eyes are mattering, one of the following three may be substituted:—

97. *Sulphate of Zinc*, ... 2 *grains.*
Water, ... 1 *ounce.*

Or,

98. *Alum*, ... 2 *grains.*
Water, ... 1 *ounce.*

Or,

99. *Bichloride of Mercury*, . . . 1 *grain.*
Water, ... 2 *ounces.*

Dissolve. This is still further diluted for use with two or three times the quantity of water.

Note.—*It is very poisonous, and must be kept out of the range of being accidentally used for internal medicine.*

Any of these four may be used as a wash for inflamed conditions of the eyelids. (Refer to *Conjunctivitis*, p. 368). When there is fear of light to any extent, and the eye cannot be opened to the light, such should not be used, but the atropine drops employed and the other treatment recommended under inflammation of the cornea (p. 371).

Eye Ointment.

100. *Yellow Precipitate*, ... 8 *grains.*
Vaseline or Lard, ... 1 *ounce.*

Mix with the aid of heat. A stronger ointment with the same ingredients is mentioned on p. 367.

101. *Weak Citrin Ointment*, . . . 1 *drachm.*
Vaseline or Lard, ... 7 *drachms.*

Mix. This is very suitable for applying to the edges of inflamed and thickened eyelids with inflammation round the lashes (see p. 367).

Hair Wash.

102. *Aromatic Spirit of Ammonia*, . . 1 *ounce.*
Spirit of Rosemary, ... 1 „
Glycerine, ... 1 „
Tincture of Cantharides (Spanish-fly), ... ½ „
Rose Water, ... *to* 8 *ounces.*

Mix. This is to be applied to the roots of the hair with a piece of sponge or a fine brush, when the hair is falling off.

Erasmus Wilson's Hair Wash.

103. *Strong Liquor Ammonia*, . . 1 *ounce.*
Spirit of Rosemary, ... 3 *ounces.*
Tincture of Cantharides, . . . 1 *ounce.*
Almond Oil, ... 1 „
Lavender Water, ... 2 *ounces.*

Use as directed for No. 102.

GLOSSARY.

Abdomen (Lat. *abdere*, to conceal), the belly, pp. 130, 138.

Abortion (Lat. *abortio*), a miscarriage, p. 513.

Abrasion (Lat. *ab*, off, and *rado*, I rub), removal of the protecting surface of the skin, p. 974.

Abscess (Lat. *abscedere*, to separate), a collection of matter, pp. 28, 209.

Absorption (Lat. *absorbere*, to suck up), the process by which materials are taken up by vessels in the body, pp. 201, 204.

Acetabulum (Lat. *acetum*, vinegar) means a vessel for holding vinegar. Applied to the socket into which the upper end of the thigh-bone fits to form the hip-joint, p. 22.

Acholia (Gr. *a*, not, and *cholē*, bile), absence of bile, p. 199.

Acromion (Gr. *akros*, high, and *omos*, the shoulder), the process of the shoulder blade which forms the point of the shoulder, p. 21.

Acute (Lat. *acutus*, sharp), applied to disease running a rapid course with severe symptoms, p. 4.

Adenitis (Gr. *adēn*, a gland), inflammation of glands, p. 207.

Adenoid (Gr. *adēn*, a gland), gland-like, p. 201.

Adipose (Lat. *adeps*, fat), applied to fatty tissue, p. 17.

Aeroscope (Gr. *aēr*, the air, and *skopeō*, I examine), an instrument for determining the presence of particles in the air, p. 685.

Ætiology (Gr. *aitia*, a cause, and *logos*, a discourse), the branch of medical science which deals with the causes of disease, p. 4.

Afferent (Lat. *ad*, to, and *fero*, I carry), nerves or vessels which convey impressions or blood or lymph towards the centre of the body, p. 291.

Agraphia (Gr. *a*, not, and *graphō*, I write), loss of power of writing, p. 120.

Albumin (Lat. *album*, white), a substance of which white of egg is a type, p. 132.

Albuminuria (Lat. *albumin*, from *album*, white, and Gr. *ouron*, the urine), albumin in the urine, p. 295.

Algide (Lat. *algeo*, to be very cold), applied to a stage of cholera, p. 188.

Alkalies (Arabic, *al*, essence, and *kali*, the plant from which soda was first obtained), compounds of certain metals, soda, potash, &c., which neutralize acids, p. 844.

Alkaloid (*alkali*, which see, and Gr. *eidos*, likeness), certain complex nitrogenous principles found in plants, such as morphia, strychnia.

Alopecia (Gr. *alopex*, a fox, in which partial loss of hair is common), loss of hair, p. 329.

Alteratives (Lat. *alter*, another), remedies which modify nutritive processes in the body, p. 822.

Alveolus, pl. **Alveoli** (Lat. *alveus*, a trough), applied to the sockets of the teeth and the air-cells of the lung, p. 252.

Amaurosis (Gr. *amauroō*, I darken), loss of sight, partial or complete, p. 378.

Amblyopia (Gr. *amblus*, dulled, and *ōps*, eye), defective vision, p. 378.

Amenorrhœa (Gr. *a*, absence of, *mēn*, the month, *reō*, I flow), absence of the monthly illness, p. 508.

Amnesia (Gr. *amnēsia*, forgetfulness), loss of memory of words, p. 120.

Amnion (Gr.), the membranous sac enclosing the fœtus, p. 485.

Amœba (Gr. *ameibō*, I change), an elementary organism, p. 214.

Ampulla (Lat. *ampulla*, a flask), a dilated portion of a canal, p. 358.

Amyloid (Lat. *amylum*, starch), starch-like, p. 200.

Anæmia (Gr. *a*, without, and *haima*, blood), the condition of poverty of blood, pp. 103, 215.

Anæsthesia (Gr. *a*, not, and *aisthanomai*, I perceive), loss of feeling, p. 118.

Anæsthetics (see above), substances which abolish sensation, p. 904.

Anasarca (Gr. *ana*, through, and *sarx*, flesh), a term for dropsy, p. 435.

Anatomy (Gr. *ana*, apart, and *temnō*, I cut), the science which deals with the structure of organized bodies, p. 15.

Anchyloblepharon (Gr. *ankulē*, a thong, and *blepharon*, the eyelid), adhesion of eyelids to one another, p. 369.

Anchylosis (Gr. *ankulos*, curved), the stiffening and fixing of a joint by disease, p. 33.

Aneurism (Gr. *aneurunō*, to widen), a tumour formed by dilatation of an artery, p. 244.

Angeioma (Gr. *angeion*, a blood-vessel), a blood-vessel tumour, p. 247.

Angina (Lat. *angina*, from *ango*, I strangle), an affection of the heart accompanied by a paroxysm of pain, p. 243.

Angioleucitis (Gr. *angeion*, a vessel, *leukos*, white, and termination *itis*), inflammation of lymphatic vessels, p. 206.

Anodynes (Gr. *a*, without, and *odunē*, pain), remedies for the relief of pain, p. 897.

Anorexia (Gr. *an*, negative, and *orexis*, appetite), want of appetite, p. 146.

Anosmia (Gr. *a*, not, and *osmē*, smell), loss of sense of smell, p. 366.

Antacids (Gr. *anti*, against, and Lat. *acidus*, acid), remedies which neutralize acids, pp. 839, 843.

Anthelmintic (Gr. *anti*, against, and *elmins*, a worm), remedies against worms, p. 871.

Anthrax (Gr. *anthrax*, a coal or carbuncle), an infectious disease specially attacking animals, but communicable to man, p. 315.

Anthropometry (Gr. *anthrōpos*, a man, and *metron*, a measure), the measurements of the physical proportions of the body, strength, weight, height, &c., p. 467.

Antidote (Gr. *anti*, against, and *didōmi*, to give in return), a medicine which counteracts the effects of a poison or destroys it, p. 1018.

Antifebrile (Gr. *anti*, against, and Lat. *febris*, fever), applied to remedies for fever, p. 820.

Antiperiodic (Gr. *anti*, against, and *periodos*, a period), remedies for diseases which have increase or return at regular intervals, such as ague, p. 823.

Antiphlogistic (Gr. *anti*, against, and *phlōgōsis*, heat), a remedy for fever, p. 820.

Antipyretic (Gr. *anti*, against, and *puretos*, fever), remedies for fever, p. 819.

Antiseptic (Gr. *anti*, against, and *sēpō*, I make putrid), substances which prevent putrefaction, p. 395.

Antispasmodics (Gr. *anti*, against, *spasmos*, a spasm), remedies to allay spasm of pain, flatulence, &c., p. 897.

Anus (Lat. *anus*, the sitting thing), the termination of the bowel, p. 130.

Aorta (Gr. *aeirō*, I take up or carry), the large artery springing from the left side of the heart, p. 219.

Aperients (Lat. *aperio*, I open), medicines which gently open the bowels, p. 856.

Aphasia (Gr. *a*, not, and *phēmi*, I speak), a disease of the brain causing loss of the faculty of speech, p. 94.

Aphemia (Gr. *a*, not, and *phēmi*, I speak), loss of faculty of speech, p. 120.

Aphonia (Gr. *a*, not, *phōnē*, the voice), loss of voice, p. 287.

Aphthæ (Gr. *aphtha*, from *aptō*, I set on fire), the patches of thrush, p. 149.

Apnœa (Gr. *a*, not, *pneō*, I breathe), temporary arrest of breathing through saturation of the blood with oxygen, p. 286.

Aponeuroses, fibrous membranes inclosing muscles, p. 73.

Arachnoid (Gr. *arachnē*, a spider's web, and *eidos*, shape), a membrane of brain and spinal cord, pp. 91, 97.

Argyria (Gr. *arguros*, silver), discoloration of the skin due to prolonged use of silver as an internal remedy.

Arthritis (Gr. *arthron*, a joint), inflammation of a joint, p. 33.

Articulation (Lat. *articulus*, a joint), a joint, p. 23.

Arytenoid (Gr. *arutaina*, a pitcher), cartilages of the box of the windpipe, p. 262.

Ascaris (Lat. *ascaris*, a worm), a round-worm, p. 173.

Ascites (Gr. *askitēs*, from *askos*, a bag), dropsy of the belly, p. 191.

Asphyxia (Gr. *asphuxia*, a stopping of the pulse), suffocation, pp. 285, 1008.

Asthenopia (Gr. *a*, not, *sthenos*, strength, *ōps*, the eye), weak-sightedness, p. 378.

Astigmatism (Gr. *a*, want of, and *stigma*, a point), a defect of the eye, causing blurred vision, p. 378.

Astragalus (Gr. *astragalos*), the bone of the ankle on which the lower leg bones rest, p. 23.

Atavism (Lat. *atavus*, a grandfather), the inheritance of some peculiarity existing in a grandparent, but absent from the parent, p. 7.

Atelectasis (Gr. *atelēs*, imperfect, and *ektasis*, widening), imperfect expansion of the lungs after birth, p. 283.

Atheroma (Gr. *athara*, gruel), a disease of arteries, p. 244.

Atonic (Gr. *a*, not, and *tonos*, tone), without tone or power.

Auditory (Lat. *audio*, I hear), belonging to the organ or sense of hearing, p. 357.

Auricle (Lat. *auricula*, a little ear), the upper chamber of each side of the heart, p. 219. The outer part of the ear, p. 356.

Auscultation (Lat. *ausculto*, I listen), a method of examining the body by listening over various parts, p. 266.

Axilla (Lat.), the arm-pit, p. 227.

B.

Bacillus (Lat. *bacillum*, a little rod), a variety of germ, pp. 387, 393.

Bacteria (Gr. *baktērion*, a little staff), a variety of germ, p. 386.

Basilic (Gr. *basilikos*, royal), applied to veins of the arm from the notion that they were of great importance to the body, p. 229.

Biceps (Lat. *bis*, twice, and *caput*, the head), applied to muscles, p. 72.

Bicuspid Teeth (Lat. *bis*, twice, and *cuspis*, a point), applied to teeth, pp. 136, 137.

Bleb (Saxon *blædr*, from *blasan*, to blow), a watery sac or vesicle, p. 313.

Blepharitis (Gr. *blepharon*, the eyelid, and *itis*, signifying inflammation), inflammation of the edge of the eyelid, p. 367.

Bothriocephalus latus (Gr. *bothrion*, a little pit, and *kephalē*, the head, Lat. *latus*, broad), a tape-worm, pp. 168, 170.

Brachial (Lat. *brachium*, the arm), belonging to the arm, p. 99.

Bromism, symptoms due to continued use of the bromides, p. 905.

Bronchiectasis (Gr. *bronchia*, bronchial tubes, and *ektasis*, widening), dilatation of bronchial tubes, p. 272.

Bronchitis (Gr. *bronchos*, and *itis*, signifying inflammation), inflammation of bronchial tubes, p. 270.

Bronchocele (Gr. *bronchos*, the windpipe, and *kēlē*, tumour), goitre, p. 210.

Bronchus (Gr. *bronchos*), applied to the two divisions of the windpipe, p. 251.

Bubo (Gr. *boubōn*, the groin), an inflammation of a lymphatic gland, usually of the groin, pp. 987, 988.

Bulimia (Gr. *bou*, indicating emphasis, and *limos*), morbid hunger, p. 146.

Bulla (Lat. *bulla*, a bubble of water), a bleb, p. 313.

Bursæ (Gr. *bursa*, a bag or purse), applied to small sacs, secreting fluid, placed over a joint or tendon to facilitate its movement and prevent friction, p. 75.

C.

Cachexia (Gr. *kakos*, bad, and *hexis*, a habit), a morbid condition of body, p. 4.

Cæcum (Lat. *cæcus*, blind), the beginning of the large intestine, p. 130.

Calcaneus (Lat. *calcaneum*, from *calx*, the heel), the bone of the heel, p. 83.

Calcareous (Lat. *calx*, lime), chalky, pp. 243, 923.

Calculus (Lat. *calculus*, a small stone, from *calx*, chalk), applied to any concretion formed in the body, p. 298.

Callus (Lat. *callus*, hardness), the material formed round the ends of a broken bone to knit them together, p. 36.

Calorie (Lat. *calor*, heat), the unit of heat, p. 529.

Calorimeter (Lat. *calor*, heat, and Gr. *metron*, a measure), an instrument for measuring amount of heat given off from a body.

Canaliculi (Lat. *canaliculus*, a small channel), small canals in bone, p. 18.

Cancellated (Lat. *cancelli*, lattice), applied to spongy bone because of the lattice-like arrangement of the bone spicules, p. 17.

Canities (Lat. *canities*, hoariness, from *canus*, gray-haired), grayness of hair, p. 329.

Capelline (from Lat. *caput*, the head), applied to a bandage for the head, p. 960.

Capillaries (Lat. *capillus*, a hair), the finest subdivisions of the blood-vessels, p. 225.

Carbo-hydrates (Lat. *carbo*, a coal, and Gr. *hudōr*, water), compounds of carbon with hydrogen and oxygen in proportions to form water, such as sugar and starches, p. 133.

Carbonaceous (Lat. *carbo*), of the nature of carbon, applied to sugary and starchy food-stuffs, p. 538.

Carcinoma (Gr. *karkinos*, a crab), a variety of cancer, p. 433.

Cardiac (Gr. *kardia*, the heart), belonging to the heart.

Caries (Lat. *caries*, rottenness), ulceration of bone, p. 26.

Carminatives (Lat. *carmen*, a song or charm), applied to remedies for flatulence, p. 848.

Carotid (from Gr. *karoō*, to throw into a heavy sleep), applied to the large arteries of the neck by the ancients from belief that they were the cause of deep sleep.

Carpus (Gr. *karpos*, the wrist), the wrist, p. 22.

Cartilage (Lat. *cartilago*), gristle, p. 23.

Casein (Lat. *caseus*, cheese), an albuminous body, the chief component of curd of milk, p. 132.

Caseous (Lat. *caseus*, cheese), cheesy. Frequently applied to morbid stuff found in inflamed glands.

Catalepsy (Gr. *katalambanō*, to attack), a disease in which sensation and consciousness are suspended and the body is rigid, p. 521.

Cataract (Gr. *katarassō*, I fall down), an affection of the lens of the eye causing blindness, p. 374.

Catarrh (Gr. *kata*, down, *reō*, I flow), inflammation of a mucous membrane attended by discharge, for example, cold in the head, p. 154.

Cathartic (Gr. *kathairō*, I purge), a variety of purgative medicines, p. 860.

Catheter (Gr. *kathetēr*, anything let down into), an instrument passed into the bladder to draw off water, p. 1050.

Cauda equina (Lat. *cauda*, a tail, *equinus*, belonging to a horse), the bundle of nerves passing off from the end of the spinal marrow, p. 97.

Cellular (Lat. *cellula*, a little cell), consisting of cells or cavities, p. 16.

Cellulose (deriv. same as above), a variety of starch, p. 537.

Cephalalgia (Gr. *kephalē*, the head, and *algos*, pain), pain in the head.

Cephalic (Gr. *kephalikos*, belonging to the head), applied to veins of the arm, p. 229.

Cerebellum (diminutive of Lat. *cerebrum*, the brain), the hind brain, p. 90.

Cerebritis (*cerebrum*, and terminal *itis*), inflammation of the brain, p. 101.

Cerebro-spinal (*cerebrum*, and *spina*, the spine), related to both brain and spinal cord, p. 89.

Cerebrum (Lat. *cerebrum*, the brain), the large brain, p. 89.

Cerumen (Lat. *cera*, wax), ear-wax, p. 356.

Cervical (Lat. *cervix*, the neck), related to the neck, p. 20.

Cestodes (Gr. *kestos*, a studded girdle, and *eidos*, likeness), tapeworms.

Chalazion (Gr. *chalaza*, hail), a tumour of eyelid, p. 368.

Chalybeate (Gr. *chalups*, iron), containing iron, as chalybeate waters, p. 947.

Chloasma (Gr. *chloaxō*, to be green), an affection of the skin, p. 322.

Chlorosis (Gr. *chlōros*, green), green-sickness, p. 235.

Chologogue (Gr. *cholē*, bile, and *agō*, I lead out), remedies which induce a flow of bile, p. 856.

Chorea (Gr. *choreia*, a dancing), St. Vitus' dance, p. 125.

Chronic (Gr. *kronikos*, concerning time), applied to long-standing disease, p. 4.

Chyle (Gr. *chulos*, juice), nutritive fluid absorbed from the bowel, p. 200.

Chyluria (*chyle*, and Gr. *ouron*, urine), chyle in the urine, p. 305.

Chyme (Gr. *chumos*, juice), the partially digested material which passes into the bowel from the stomach, p. 129.

Cicatrix (Lat. *cicatrix*, a scar), the scar of a healed wound, p. 968.

Cilium (plural *cilia*, Lat. *cilium*, an eyelash), applied to minute hair-like processes on cells, p. 16.

Cirrhosis (Gr. *kirros*, yellow), originally applied to a disease of the liver, now applied to thickening of connective tissue of any organ, p. 196.

Clavicle (Lat. *clavicula*, a little key), the collar-bone, p. 21.

Clonic (Gr. *klonos*, commotion), of an irregular movement, jerking.

Clysters (Gr. *kluzō*, I wash away), an injection into the bowel, p. 873.

Coccyx (Gr. *kokkux*, the cuckoo), the four rudimentary bones united together and forming the end of the backbone in man; called *os coccygis*, or bone of the cuckoo, from a supposed resemblance to the bill of the cuckoo, p. 20.

Cœliac (Gr. *koilia*, the belly), belonging to the belly.

Colloid (Gr. *kolla*, glue), a term applied by Graham to insoluble non-crystalline organic substances which cannot pass through organic membranes, such as starch, p. 134.

Colon (Gr. *kolon*, food), part of the large bowel, p. 130.

Colostrum (Lat. *colostrum*), the first milk in the breasts after delivery.

Columnæ carneæ (Lat., meaning fleshy pillars), applied to muscular projections on inner wall of heart, p. 222.

Coma (Gr. *kōma*, deep sleep), deep sleep of an unnatural kind, the person being incapable of being roused to consciousness, p. 102.

Comedones (Lat. *comedo*, a glutton), the black-pointed mattery substance that can be squeezed out of the hair-sacs of cheeks, forehead, and nose, p. 327.

Commissure (Lat. *committo*, I join together), a bond of connection.

Condyle (Gr. *kondulos*, a hard knob), a prominent part of a bone in connection with a joint, p. 23.

Congenital (Lat. *con*, together, and *genitus*, begotten), applied to any disease or malformation, &c., existing at birth, p. 3.

Conjunctiva (Lat. *con*, together, and *jungo*, I join), the membrane which lines the inner surface of the eyelids and is reflected on to the eyeball, p. 339.

Conjunctivitis (Lat. *conjunctiva*, and terminal *itis*), inflammation of the conjunctiva, p. 368.

Contagion (Lat. *con*, together, *tango*, I touch), the communication of disease by the transference from the diseased person to another of the special seed or germ of the disease by contact direct or indirect, p. 384.

Contusion (Lat. *con*, together, and *tundo*, I beat), a bruise, p. 974.

Convalescence (Lat. *convalesco*, to grow well), the stage of recovery from illness.

Coracoid (Gr. *korax*, a raven, and *eidos*, likeness), applied to a process of the shoulder-blade, from a supposed resemblance to a crow's beak.

Corium (Lat. *corium*, the skin), the true skin, p. 307.

Cornea (Lat. *cornu*, a horn), the transparent part of the front of the eyeball, p. 339.

Coronary (Lat. *corona*, a crown), applied to vessels that encircle parts. Coronary vessels of heart, p. 219.

Coronoid (Gr. *korōne*, a crow, and *eidos*, likeness), applied to processes of lower jaw (p. 22) and lower end of upper arm-bone.

Corpora Quadrigemina (Lat. *corpus*, a body, and *quadrigeminus*, fourfold), ganglia at base of brain, p. 90.

Corpora Striata (Lat. for striated bodies), ganglia at base of brain, p. 90.

Corpus Callosum (Lat. for thick-skinned body), a transverse mass of nervous substance connecting the two hemispheres of the brain, p. 89.

Corpuscle (Lat. *corpusculum*, diminutive of *corpus*, a body), small cellular bodies, as the cells of the blood, p. 213.

Coryza (from Gr. *korus*, the head), cold in the head, p. 154.

Costal (Lat. *costa*, a rib), related to the ribs, p. 256.

Cranium (Gr. *kranion*, the skull), the skull; that part of the head distinguished from the face, p. 19.

Crepitation (Lat. *crepitus*, a crackling), the feeling of grating of the two ends of a broken bone, p. 40. It is applied also to the sound heard in the lungs on listening over the chest when material is present in the lungs, as in inflammation.

Cribriform (Lat. *cribrum*, a sieve, and *forma*, shape), applied to a part of the ethmoid bone, p. 19.

Cricoid (Gr. *krikos*, a ring, and *eidos*, likeness), applied to a part of the box of the windpipe, p. 250.

Crural (Lat. *crus*, the leg), belonging to the leg, p. 192.

Cuneiform (Lat. *cuneus*, a wedge), a bone of the wrist, pp. 22, 23.

Cuticle (Lat. *cuticulus*, diminutive of *cutis*, the skin), the scarf-skin, p. 307.

Cyanosis (Gr. *kuanōsis*, a dark-blue colour), lividity, p. 244.

Cyst (Gr. *kustis*, the bladder), a sac filled with more or less fluid contents.

Cysticercus (Gr. *kustis*, the bladder, and *kerkos*, a tail), the bladder-worm, a stage in the development of tape-worm, p. 169.

Cystitis (*cyst*, and termination *itis*), inflammation of the urinary bladder, p. 305.

D.

Deglutition (Lat. *deglutio*, I swallow down), the act of swallowing, p. 143.

Dementia (Lat. *de*, negative, and *mens*, the mind), a species of insanity, p. 109.

Dental (Lat. *dens*, a tooth), belonging to a tooth, p. 137.

Dermis (Gr. *derma*, the skin), the true skin, p. 307.

Desquamation (Lat. *desquamo*, I scale off, from *de*, away, and *squama*, a scale), a scaling or peeling of the scarf-skin, p. 313.

Diabetes (Gr. *dia*, through, and *bainō*, I go on), a disease in which a large quantity of urine containing sugar is passed, p. 147.

Diagnosis (Gr. *dia*, between, and *gnōsis*, knowledge), the determining a disease by means of the observation of symptoms, &c., p. 8.

Diaphoretics (Gr. *diaphoreō*, to carry across), drugs which increase the amount of sweat, p. 887.

Diaphragm (Gr. *diaphragma*, a partition), the tendinous and muscular partition between chest and belly, p. 253.

Diarrhœa (Gr. *dia*, through, and *reō*, I run), the disease characterized by very frequent fluid motions, p. 184.

Diastase (Gr. *diastasis*), a ferment formed in grain during germination, p. 666.

Diastasis (Gr. *diastasis*, a separation), applied to the separation of the ends from the shaft of growing bone, p. 35.

Diastole (Gr. *diastellō*, I open) applied to the dilatation of the cavities of the heart, p. 224.

Diathesis (Gr. *diathesis*, a placing in order, a state or condition), a condition of body rendering it liable to certain special diseases; for example, a gouty diathesis, p. 7.

Digastric (Gr. *dis*, double, and *gastēr*, the belly), two-bellied; applied to a muscle, p. 70.

Digit (Lat. *digitus*, a finger), a finger or toe. *Digital*, belonging to fingers or toes.

Diploë (Gr. *diploē*, a fold), the spongy bone between the outer and inner tables of bone making the thickness of the skull bone.

Diplopia (Gr. *diploos*, double, and *opsis*, sight), double sight, seeing double, p. 379.

Dipolar (Gr. *dis*, double, and *polŏs*, the axis of a globe), two-poled; applied to nerve-cells, p. 85.

Dipsomania (Gr. *dipsa*, thirst, and *mania*, madness), the unconquerable craving for drink, p. 105.

Disinfection (Lat. *dis*, negative, and *inficio*, I corrupt), the destruction of infective material, p. 395.

Diuretics (Gr. *dia*, through, and *oureō*, I pass water), drugs which increase the flow of urine, p. 890.

Dorsal (Lat. *dorsum*, the back), belonging to the back, pp. 20, 99.

Drastic (Gr. *drastikos*, active, from *draō*, I do), applied to vigorous purgative medicines, p. 861.

Duodenum (Lat. *duodeni*, twelve apiece), the first part of the small intestine, about 12 inches long.

Dura Mater (Lat., meaning hard mother), applied to the external membrane investing brain and spinal cord; old idea being that it gave origin to all other membranes of the body, and it is of tough quality, p. 91.

Dysmenorrhœa (Gr. *dus*, difficulty, *mēn*, a month, and *reō*, I flow), painful monthly illness, p. 510.

Dyspareunia (Gr. *duspareunos*, ill-mated), difficult or painful performance of the sexual function, p. 519.

Dysphagia (Gr. *dus*, and *phagein*, to eat), difficulty of swallowing, p. 157.

Dysphonia (Gr. *dus*, and *phonē*, the voice), imperfect voice, p. 287.

Dyspnœa (Gr. *dus*, and *pneō*, I breathe), difficulty of breathing, p. 284.

E.

Ecchymosis (Gr. *ek*, out, and *cheō*, I pour), an effusion of blood into the skin or tissue beneath it, producing the well-known discoloration of a bruise, p. 974.

Ectropion (Gr. *ektrepō*, to divert), applied to the turning outwards of the inner surface of the eyelid, p. 367.

Eczema (Gr. *ekzema*, something thrown out by heat, from *ekzeō*, I boil over), a skin disease, p. 318.

Efferent (Lat. *e* or *ex*, out, and *fero*, I carry), outgoing; applied to vessels or nerves carrying material or impressions from the centre to the circumference of the body, p. 87.

Effleurage (French, *effleurer*, to touch lightly), a variety of stroke in massage, p. 772.

Efflorescence (Lat. *effloresco*, I flourish), a flowering; applied in medicine to the rash of fevers.

Embolism (Gr. *emballō*, I throw in), applied to the obstruction of a blood-vessel by something carried to it in the blood stream. The obstructing thing is called an *embolus*, p. 102.

Embrocation (Gr. *embrechō*, I soak in), a fluid for external application to a part.

Embryo (Gr. *embruon*, from *em*, in, and *bruō*, I swell with), the rudiment of a living thing; applied to the growing offspring before the fourth month of pregnancy, p. 485.

Emetic (Gr. *emeō*, I vomit), applied to substances which induce vomiting, p. 850.

Emphysema (Gr. *emphusēma*, an inflation), applied to an over-distended condition of air-cells of the lungs, p. 271.

Emprosthotonus (Gr. *emprosthen*, forwards, and *teinō*, I stretch), a condition in which, by spasmodic contraction of muscles, the body is bent forwards, p. 126.

Empyema (Gr. *em*, within, and *puon*, pus, matter), a collection of matter in the chest cavity, p. 267.

Emunctory (Lat. *emungo*, I blow the nose), applied to organs or channels by which effete matter is removed from the body.

Encephaloid (Gr. *encephalos*, the brain, *eidos*, likeness), brain-like, p. 434.

Encephalon (Gr. *en*, in, and *kephalē*, the head), the parts within the skull, p. 89.

Endemic (Gr. *en*, in, and *dēmos*, a people), applied to a disease peculiar to a people or neighbourhood from some cause special to it, p. 4.

Endocarditis (Gr. *endon*, within, *kardia*, the heart, and terminal *itis*), inflammation of the inner lining membrane of the heart, p. 239.

Endocardium (same deriv. as above), the inner lining membrane of the heart, p. 220.

Endolymph (Gr. *endon*, within, and Lat. *lympha*, water), applied to fluid in canals of inner ear, p. 358.

Endosmosis (Gr. *endon*, and *ōsmos*, a pushing in), the process by which a substance in solution passes to the inner side of an organic membrane, p. 134.

Endosteum (Gr. *endon*, and *osteon*, a bone), the lining membrane of the marrow cavity of a bone, p. 18.

Endostitis (same deriv. as above, with terminal *itis*), inflammation of endosteum, p. 27.

Enema (Gr. *enema*, from *eniēmi*, to inject), an injection, p. 873.

Enteric (Gr. *enteron*, the bowel), belonging to the bowels. See enteric fever, p. 411.

Enteritis (same deriv. as *enteric*, with terminal *itis*), inflammation of bowel, p. 162.

Entropion (Gr. *en*, in, and *trepō*, I turn), a turning in of the eyelid, p. 367.

Epidemic (Gr. *epi*, upon, *dēmos*, a people), applied to disease prevalent among a people, and due to a special cause not commonly present, p. 4.

Epidermis (Gr. *epi*, upon, and *derma*, the skin), the scarf-skin, p. 307.

Epigastrium (Gr. *epi*, upon, and *gastēr*, the stomach), the region of the belly over the stomach, the epigastric region, p. 131.

Epiglottis (Gr. *epi*, upon, and *glottis*, the upper opening of the windpipe), the structure that acts as a lid to the windpipe, p. 136.

Epiphyses (Gr. *epi*, upon, and *phuō*, I grow), applied to the ends of a long bone, which in development become ossified apart from the shaft, p. 18.

Epispastics (Gr. *epi*, upon, and *spaō*, I draw), remedies which blister, p. 914.

Epistaxis (Gr. *epi*, upon, and *stazō*, I let fall in drops), bleeding from the nostrils, p. 366.

Epithelioma (Gr. *epi*, upon, and *thēlē*, the nipple), skin cancer, p. 434.

Epithelium (Gr. *epi*, upon, and *thēlē*, a nipple), the layer or layers of cells forming the surface layer of skin or mucous membrane, p. 16.

Eructation (Lat. *eructo*, I belch), a belching of wind from the stomach.

Erythema (Gr. *eruthainō*, I make to blush), a slight inflammation, redness of skin, p. 313.

Ethmoid (Gr. *ēthmos*, a sieve, and *eidos*, likeness), a bone of the skull, p. 19.

Exanthemata (Gr. *exanthēma*, an eruption), infectious fevers attended by rash, p. 397.

Excoriation (Lat. *ex*, out of, and *corium*, the skin), an abrasion.

Excreta (Lat. *excerno*, I sift out), effete material removed from the body.

Exophthalmia (Gr. *ex*, out, and *ophthalmos*, the eye), protrusion of the eyeball.

Exostosis (Gr. *ex*, out, and *osteon*, a bone), a bony outgrowth from bone due to disease, p. 27.

Expectorant (Lat. *ex*, out of, and *pectus*, the breast), remedies which promote the expulsion of material from lungs and air-passages, p. 879.

Expectoration (Lat. *ex*, out of, and *pectus*, the breast), spitting out material from mouth, throat, lungs, &c., and also the material so expelled.

Extravasation (Lat. *extra*, outside of, and *vasa*, vessels), the pouring out among the tissues from a cavity or vessel of its fluid contents, p. 974.

Exudation (Lat. *ex*, out, and *sudo*, I sweat), oozing of fluid through the walls of the vessel or receptacle which contains it; also the material which exudes, p. 248.

F.

Fæces (Lat. *fæx*, sediment), motions from the bowel.

Farinaceous (Lat. *farina*, flour), applied to starchy food-stuffs, p. 584.

Fascia (Lat. *fascia*, a band), applied to the fibrous tissue investing muscles, &c., p. 67.

Fauces (Lat. for the upper part of the throat), the cavity at the back of the mouth, p. 136.

Febrifuge (Lat. *febris*, fever, and *fugo*, I drive away), applied to remedies for fever, p. 820.

Femoral (Lat. *femur*, the thigh), belonging to the thigh, p. 228.

Femur (Lat. for the thigh), the thigh-bone, p. 23.

Fibula (Lat. *fibula*, a brooch), the clasp-bone, the outer bone of the foreleg, p. 23.

Fission (Lat. *fissio*, a dividing), the process of cleavage in cell reproduction, p. 387.

Fistula (Lat. *fistula*, a tube), an unnatural channel leading from the outside of the body inwards, p. 500.

Flatulence (Lat. *flatus*, a breath), wind in stomach or bowels.

Fluctuation (Lat. *fluctus*, a wave), the wave-like feeling communicated to the fingers when a cavity containing fluid is smartly tapped, p. 32.

Fœtus (Lat. *fœtus*, offspring), applied to the child in the womb in the later months, p. 485.

Furunculus (Lat.), a boil, p. 365.

G.

Ganglion, pl. **Ganglia** (Gr. *ganglion*, a tumour under the skin), an enlargement in the course of a nerve, containing nerve-cells as well as nerve-fibres, pp. 78, 85.

Gangrene (Gr. *grainō*, I gnaw), death of tissue in mass, p. 248.

Gastralgia (Gr. *gastēr*, stomach, and *algos*, pain), pain at the region of the stomach. Same as gastrodynia.

Gastric (Gr. *gastēr*, the stomach), related to the stomach.

Gastritis (Gr. *gastēr*, and terminal *itis*), inflammation of the stomach, p. 157.

Gastrocnemius (Gr. *gastēr*, the belly, and *knēmē*, the leg), the muscle of the calf of the leg, p. 74.

Gastrodynia (Gr. *gastēr*, and *odunē*, pain), pain in the stomach, p. 181.

Gastro-enteritis (Gr. *gastēr*, and *enteron*, the bowel), inflammation of both stomach and bowel.

Genu-valgum (Gr. *gonu*, the knee, and Lat. *valgus*, having the legs bent outwards), knock-knee, p. 83.

Gland (Lat. *glans*, an acorn), an organ for manufacturing some material for the blood for subsequent use in the body or for removal from the body, or which takes part in blood formation, p. 201, 204.

Glaucoma (Gr. *glaukos*, denoting a greenish-yellow colour), a disease of the eye causing blindness, p. 375.

Glenoid (Gr. *glēnē*, the pupil or eyeball, and *eidos*, likeness), applied to a depression in one bone to receive the head of another, p. 21.

Glomerulus (Lat., diminutive of *glomus*, a small ball), applied to the tufted arrangement of vessels in the kidney, p. 290.

Glosso-pharyngeal (Gr. *glossa*, the tongue, and *pharunx*, the throat), connected with tongue and throat, applied to one of the cranial nerves, p. 90.

Glottis (Gr. *glottis*, the upper opening of the windpipe), the opening in the box of the windpipe between the vocal cords, p. 262.

Gluteus (Gr. *gloutos*, the buttock), belonging to the buttock; applied to muscles, nerves, and vessels, p. 73.

Glycogen (Gr. *glukus*, sweet, and *gennaō*, I produce), animal starch, p. 147.

Glycosuria (Gr. *glukus*, sweet, and *ouron*, urine), sugar in urine, p. 303.

Granulation (Lat. *granum*, a grain), applied to the small bright grain-like fleshy elevations that appear on a healing wound; also to the process by which open wounds heal.

Gumma, pl. **Gummata** (Lat. *gumma*, gum), small tumours that occur in various tissues as a consequence of syphilis, p. 424.

Gustatory (Lat. *gusto*, I taste), relating to taste, as gustatory nerve, the nerve of taste, p. 337.

H.

Hæmatemesis (Gr. *haima*, blood, and *emeō*, I vomit), vomiting of blood, p. 159.

Hæmatinuria (Gr. *hæmatin*, the colouring matter of blood, and *ouron*, urine), passage of urine containing the colouring matter of blood, p. 304.

Hæmaturia (Gr. *haima*, blood, and *ouron*, urine), blood in the urine, p. 304.

Hæmophilia (Gr. *haima*, blood, and *philia*, fondness for), a disposition to bleeding, p. 238.

Hæmoptysis (Gr. *haima*, and *ptusis*, spitting), blood-spitting, the blood being from the lungs, p. 282.

Hæmorrhage (Gr. *haima*, and *rēgnumi*, I break forth), escape of blood from the vessels.

Hæmorrhoids (Gr. *haima*, and *reō*, I flow), piles, p. 193.

Hemeralopia (Gr. *hēmera*, the day, and *ōps*, the eye), blindness, except in daylight, p. 378.

Hemiopia (Gr. *hemisus*, half, and *ōps*, the eye), a condition in which only one half of an eye has perception of things.

Hemiplegia (Gr. *hemisus*, half, and *plēgē*, a stroke), paralysis of motion on one side of the body, p. 118.

Hepatic (Gr. *hēpar*, the liver), belonging to the liver.

Hepatitis (Gr. *hēpar*, the liver, and *itis*), inflammation of the liver, p. 196.

Hirsuties (Lat. *hirsutus*, hairy), an unnatural development of hair, p. 329.

Hordeolum (Lat. *hordeolus*, diminutive of *hordeum*, barley), a sty in the eye, p. 368.

Humerus (Lat.), the upper arm bone, p. 21.

Hyaline (Gr. *hualos*, glass), transparent like glass. See hyaline cartilage, p. 24.

Hybernation (Lat. *hibernus*, belonging to winter), the dormant state into which certain animals and plants fall with a low temperature, p. 113.

Hydatid (Gr. *hudatis*, a watery sac), a stage in the development of tape-worm, p. 172.

Hydragogue (Gr. *hudōr*, water, and *agō*, I lead out), remedies which cause a watery discharge from the bowels.

Hydrocele (*hudōr*, and *kēlē*, a tumour), a tumour with watery contents connected with external generative organs.

Hydrocephalus (Gr. *hudōr*, water, and *kephalē*, the head), water in the head, p. 101.

Hydrometer (Gr. *hudōr*, and *metron*, a measure), an instrument for determining specific gravity of watery fluids.

Hydronephrosis (Gr. *hudōr*, and *nephros*, the kidney), dropsy of the kidney, p. 299.

Hydropericardium (Gr. *hudōr*, water, *peri*, about, and *kardia*, the heart), dropsy of the heart, p. 435.

Hydrothorax (Gr. *hudōr*, and *thorax*, the chest), dropsy of the chest.

Hygiene (Gr. *hugieinos*, good for the health), the science of the laws of health, p. 522.

Hygroscopic (Gr. *hugros*, moist, and *skopeō*, I look at), having the property of absorbing moisture.

Hyoid (Gr. *huoeidēs*, shaped like the Greek letter upsilon), applied to the bone at the root of the tongue, p. 250.

Hyperæmia (Gr. *huper*, in excess, and *haima*, blood), an excess of blood in a part, p. 235.

Hyperæsthesia (Gr. *huper*, and *aisthēsis*, a feeling), oversensibility, p. 364.

Hypermetropia (Gr. *huper*, *metron*, a measure, and *ōps*, the eye), longsightedness.

Hypertrophy (Gr. *huper*, and *trophē*, nourishment), overgrowth, p. 76.

Hypnotics (Gr. *hupnos*, sleep), drugs which procure sleep, p. 904.

Hypochondriasis (*hupochondriakos*, one affected in hypochondriac region), a form of melancholy in which the person believes himself to be suffering now from one disease, now from another. The cause of the disease was of old referred to the hypochondriac region.

Hypochondrium (Gr. *hupo*, under, and *chondros*, gristle, under the gristly part of the ribs), the regions of the body on the right and left side below the ribs.

Hypodermic (Gr. *hupo*, under, and *derma*, the skin), put under the skin.

Hypogastric (Gr. *hupo*, and *gastēr*, the stomach), referring to the region below that where the stomach is placed, p. 131.

Hypoglossal (Gr. *hupo*, and *glōssa*, the tongue), beneath the tongue, p. 90.

I.

Ichthyosis (Gr. *ichthus*, fish), fish-skin disease, p. 320.

Icterus (Gr. *ikteros*, jaundice), yellowness of skin due to jaundice, p. 198.

Ileo-cæcal (Gr. *eileō*, I turn about, Lat. *cæcum*, blind), applied to the junction between the ileum, end of the small bowel, and cæcum, head of the large bowel, p. 130.

Ileum (Gr. *eileō*, I turn about), applied to the small bowel from its windings, p. 130.

Iliacus (Lat. *ilia*, the flanks), applied to a muscle in the hollow of the ilium, p. 73.

Ilium (Lat. *ilia*, the flanks), part of the bone of the haunch, p. 22.

Impetigo (Lat. *impetigo*, a scabby eruption of the skin), a pustular disease of the skin, p. 319.

Incisor (Lat. *incido*, I cut), applied to the cutting teeth, p. 136.

Incubation (Lat. *incubo*, to sit on eggs), applied in medicine to the period between the introduction of the germs of a disease into the body and the time of first appearance of its symptoms, during which period the disease is being hatched, p. 397.

Infundibulum (Lat. *infundibulum*, a funnel, from *infundo*, I pour in), applied to the passage from which the air-cells of the lungs open, p. 252.

Infusoria (Lat. *infundo*, I pour in), applied to minute organisms first observed in infusions of organic substances, p. 385.

Inguinal (Lat. *inguen*, the groin), belonging to the groin, p. 192.

Inhibitory (Lat. *inhibitus*, a restraining), applied to the restraining influence of one nervous action over another, p. 233.

Innominate (Lat. *in*, negative, and *nomen*, a name), The unnamed bone, haunch-bone, p. 22.

Inoculation (Lat. *inoculo*, I ingraft), the introduction into the body by a wound of the skin of the poison of some disease, p. 405.

Insalivation (Lat. *in*, in, and *saliva*, the spittle), the process of mixing the food with saliva in the mouth, p. 142.

Insolatio (Lat. *insolo*, I place in the sun), sunstroke, p. 1003.

Insomnia (Lat. *in*, negative, and *somnus*, sleep), sleeplessness, p. 116.

Intercostal (Lat. *inter*, between, and *costa*, a rib), applied to structures between the ribs, p. 255.

Intermittent (Lat. *intermitto*, I leave off for a time), applied to diseases which disappear and return again after a variable time, p. 427.

Interossei (Lat. *inter*, and *os*, a bone), situated between bones. See interossei muscles, p. 73.

Intussusception (Lat. *intus*, within, and *suscipio*, I receive), applied to the passage of a part of the bowel within another part, p. 164.

Inunction (Lat. *inungo*, I anoint), the rubbing of an oily substance into the skin, p. 824.

Invagination (Lat. *in*, in, and *vagina*, a sheath), same as intussusception, p. 165.

Iodism, symptoms produced by the taking of iodine in too large or long-continued doses, p. 1020.

Iridectomy (Gr. *iris*, a rainbow, and *ektemnō*, I cut out), an operation for removing a portion of the coloured ring of the eyeball to improve sight, p. 372.

Iritis (Gr. *iris*, and terminal *itis*), inflammation of the iris of the eye, p. 373.

Ischium (Gr. *ischion*, the seat-bone), the seat-bone, p. 22.

J.

Jejunum (Lat. *jejunus*, empty), applied to a portion of the small bowel, believed to be generally found empty after death, p. 130.

Jugular (Lat. *jugulum*, the throat), belonging to the throat, p. 228.

K.

Keratitis (Gr. *keras*, a horn, and terminal *itis*), inflammation of the cornea of the eye, p. 371.

L.

Lachrymal (Lat. *lachryma*, a tear), relating to tears, such as the tear-gland, p. 339.

Lacteal (Lat. *lac*, milk), applied to vessels because of the milky juice contained, p. 145.

Lactometer (Lat. *lac*, and Gr. *metron*, a measure), an instrument for gauging quality of milk, p. 551.

Lacuna (Lat. *lacuna*, a cavity), cavities in bone occupied by bone cells, p. 18.

Lardaceous (Lat. *lardum*, the fat of bacon), applied to a certain form of tissue degeneration, p. 200.

Laryngismus (Gr. *larungizō*, I vociferate), an affection of the box of the windpipe, so called from the peculiar sound of the cry produced in it, p. 273.

Laryngitis (Gr. *larunx*, the upper part of the windpipe, and *itis*), inflammation of the box of the windpipe, p. 269.

Laryngoscope (*larynx*, and Gr. *skopeō*, I look at), an arrangement of mirrors for viewing the larynx, p. 263.

Laryngotomy (*larynx*, and Gr. *temnō*, I cut), the operation of opening the box of the windpipe from outside, p. 262.

Latissimus (Lat. for "very broad"), applied to a muscle of the back, p. 71.

Laxative (Lat. *laxo*, I loosen), opening medicines, p. 856.

Leucocytes (Gr. *leukos*, white, and *kutos*, a cell), white-cells, p. 213.

Leucocythæmia (Gr. *leukos*, *kutos*, and *haima*, the blood), white-celled blood, p. 235.

Leucorrhœa (Gr. *leukos*, and *roia*, a flow), white discharge from the female genital organs, p. 499.

Leukæmia (Gr. *leukos*, white, and *haima*, the blood), same as leucocythæmia, p. 235.

Lientery (Gr. *leios*, smooth, and *enteron*, the bowel), a species of diarrhœa, p. 185.

Ligament (Lat. *ligo*, a tie), a connecting band, p. 23.

Locomotor ataxia (Lat. *locus*, a place, and *moto*, I move, Gr. *a*, wanting, and *taxis*, order), a nervous disease characterized by unsteadiness of gait, p. 121.

Lumbar (Lat. *lumbi*, the loins), applied to the region of the loins, p. 28.

Lymphadenoma (Lat. *lympha*, water, and Gr. *adēnē*, a gland), a disease affecting lymphatic glands and producing great pallor, p. 210.

Lymphangitis (Lat. *lympha*, Gr. *angeion*, a vessel, and terminal *itis*), inflammation of lymphatic vessels, p. 206.

Lymphoma (same as *Lymphadenoma*).

Lysis (Gr. *luo*, I dissolve), the gradual decline of fever as distinct from crisis, p. 397.

M.

Malar (Lat. *mala*, the cheek-bone, from *mando*, I chew), belonging to the cheek-bone, p. 19.

Malaria (Lat. *malus*, bad, *aer*, air), the atmosphere of fever-producing marshy districts.

Malleolus (Lat. *malleus*, a hammer), projections of the lower leg-bones at the ankle, p. 23.

Masseter muscles (Gr. *massaomai*, I chew), applied to muscle of the jaw, p. 70.

Mastication (same deriv. as *masseter*), the act of chewing, p. 142.

Mastoid (Gr. *mastos*, a nipple, and *eidos*, likeness), applied to a nipple-shaped process of the temporal bone, p. 19.

Maxillary (Lat. *maxilla*, a jaw), belonging to the jaw, p. 19.

Medulla (Lat. *medulla*, marrow, for *medius*, middle), the marrow of bone (p.17), or spinal marrow (p. 96).

Medullitis, inflammation of the medulla, p. 27.

Melæna (Gr. *melas*, black), black motions, due to the presence of blood, p. 166.

Meninges (Gr. *mēninx*, a membrane), applied to membranes of brain, p. 91.

Meningitis, inflammation of membranes of brain, p. 100.

Menorrhagia Gr. *mēn*, a month, and *rēgnumi*, I burst forth), excessive monthly flow, p. 509.

Menses (Lat. *mensis*, a month), the monthly discharge, p. 481.

Menstruation (Gr. *mēn*, a month, and *reō*, I flow), the process of the monthly illness, p. 481.

Mesentery (Gr. *mesos*, middle, and *enteron*, intestine), a membrane connected with the intestine, pp. 131, 191. *Mesenteric*, belonging to the mesentery.

Metacarpal (Gr. *meta*, beyond, and *carpus*, the wrist), applied to the bones between the wrist and finger bones, the bones of the palm, p. 22.

Metatarsal (Gr. *meta*, beyond, and *tarsos*, the instep), applied to the bones between ankle and toes, p. 23.

Metrorrhagia (Gr. *mētra*, the womb, and *rēgnumi*, I burst forth), a discharge of blood from the womb at other than the monthly periods, p. 509.

Microbe (Gr. *micros*, small, and *bios*, life), same as micro-organism.

Micro-coccus (Gr. *mikros*, and *kokkos*, a berry), a form of germ, p. 387.

Micro-organisms (Gr. *mikros*), small living organisms, p. 387.

Microphytes (Gr. *mikros*, small, and *phutos*, a plant), the same meaning as micro-organisms, p. 387.

Microzymes (Gr. *mikros*, and *zumē*, yeast), applied to minute organisms, because they cause fermentation, p. 387.

Molars (Lat. *mola*, a mill), grinding teeth, p. 136.

Monomania (Gr. *monos*, single, and *mania*, madness), that form of insanity in which the aberration is in regard to one subject only, p. 108.

Morphinomania (*morphia* and *mania*), the craving for morphia, p. 1026.

Multipolar (Lat. *multus*, many, and *polos*, an axis), applied to cells with many processes, p. 85.

Myelitis (Gr. *muelos*, marrow, and terminal *itis*, inflammation), inflammation of the spinal cord, p. 117.

Myopia (Gr. *muō*, I shut or blink, and *ōps*, the eye), short-sightedness, p. 347.

N.

Nævus (Lat. *nævus*, a spot), a mother's mark, p. 247.

Narcotics (Gr. *narka*, deep sleep), p. 904.

Nausea (Gr. *nausia*, sickness, from *naus*, a ship, in relation to sea-sickness), a feeling of sickness, p. 12.

Necrosis (Gr. *nekros*, dead), death of bone, p. 26.

Nematode (Gr. *nema*, a thread, and *eidos*, likeness), a round-worm, p. 167.

Nephritis (Gr. *nephros*, the kidney, and *itis*), inflammation of the kidney, p. 295.

Neurilemma (Gr. *neuron*, a nerve, and *lemma*, a skin), the connective tissue investment of nerve-fibres, p. 85.

Neuritis (Gr. *neuron*, and *itis*), inflammation of a nerve.

Neuroglia (Gr. *neuron*, a nerve, and *glia*, glue), the connective tissue ground-substance of nervous tissue, p. 91.

Neuroma (Gr. *neuron*, a nerve), a nerve tumour.

Neurosis (deriv. as above), a nervous affection without discoverable structural change or material cause. A functional disorder.

Nyctalopia (Gr. *nux*, night, *alaos*, blind, and *ōps*, the eye), night blindness.

Nystagmus (Gr. *nustazō*, I nod), an involuntarily rolling motion of the eye-ball, p. 376.

O.

Obturator (Lat. *obturo*, to stop up), applied to an opening in the pelvis, and to muscles, vessels, and nerves passing through it.

Occipital (Lat. *occiput*, the back of the head), p. 19.

Odontoid (Gr. *odous*, a tooth, and *eidos*, likeness), applied to a process of the second cervical vertebra, p. 21.

Œdema (Gr. *oideō*, I swell), dropsy of the cellular tissue, p. 435.

Œsophagus (Gr. *oisō*, I bear, and *phagein*, to eat), the gullet, p. 157.

Olecranon (Gr. *ōlenē*, the ulna, and *kranon*, head), applied to a process of the head of the ulna, one of the fore-arm bones, p. 22.

Olfactory (Lat. *oleo*, I smell, and *facio*, I make), related to the sense of smell, p. 90.

Onychia (Gr. *onuz*, the nail), inflammation of the nail, p. 330.

Ophthalmia (Gr. *ophthalmos*, the eye), applied to certain inflammations of the eye, p. 368.

Ophthalmoscope (Gr. *ophthalmos*, the eye, and *skopeō*, I view), an instrument for examining the interior of the eye, p. 376.

Opiate (Gr. *opion*, from *opos*, a vegetable juice), a drug containing opium, or one which induces sleep, p. 897.

Opisthotonus (Gr. *opisthen*, backwards, and *teinō*, I draw), a state of spasm in which the body is bent backwards like a bow, pp. 126, 1028.

Os calcis (Lat. for the bone of the heel, *calx*, the heel), p. 23.

Os coccyx (Lat. for the coccyx bone). See Coccyx.

Os magnum (Lat. for large bone), a bone of the wrist, p. 22.

Os sacrum (Lat. for sacred bone, because it was formerly offered in sacrifice), a part of the backbone, p. 22.

Ossification (Lat. *os*, a bone, and *facio*, I make), the process of bone formation, p. 18.

Osteomalachia (Gr. *osteon*, a bone, *malakos*, soft), softening of bone, p. 31.

Osteomyelitis (Gr. *osteon*, a bone, and *muelos*, marrow), inflammation of the marrow of bone, p. 25.

Ostitis (Gr. *osteon*, a bone, and *itis*, signifying inflammation), inflammation of bone, p. 25.

Otitis (Gr. *ous*, the ear, and *itis*), inflammation of the ear.

Otoliths (Gr. *ous*, the ear, and *lithos*, a stone), small bony bodies found in the inner ear of some animals, p. 358.

Oxidation (Gr. *oxus*, acid), the process of uniting with oxygen, p. 527.

Oxyuris (Gr. *oxus*, sharp, and *ouron*, a tail), applied to a genus of thread-worms, p. 174.

Ozæna (Gr. *ozē*, a foul smell), stink-nose, p. 365.

P.

Paræsthesia (Gr. *para*, implying irregularity, and *aisthēsis*, sensation), a disorder of sensation. See p. 364.

Paraplegia (Gr. *para*, incompletely, and *plēssō*, I strike), paralysis of the lower limbs, p. 119.

Paresis (Gr. *pariēmi*, I relax), a slight degree of paralysis, p. 118.

Parietal (Lat. *paries*, a wall), applied to bones situated on the side of the head, p. 19.

Parotid (Gr. *para*, near, and *ous*, the ear), applied to a salivary gland in the neighbourhood of the ear, p. 137.

Parotitis, inflammation of the parotid gland—mumps, p. 153.

Patella (Lat. *patella*, a dish), the knee-pan, p. 23.

Pathology (Gr. *pathos*, suffering, and *logos*, discourse), the science which treats of the nature, cause, &c., of disease, p. 54.

Pectoralis (Lat. *pectus*, the breast), related to the breast, p. 71.

Pediculus (Lat. diminutive of *pedis*, a louse), a louse, p. 324.

Pelvis (Lat. *pelvis*, a basin), the cavity formed by the haunch-bones, p. 20.

Pemphigus (Gr. *pemphix*, a bladder), a disease of the skin, p. 317.

Percussion (Lat. *percutio*, I strike), a method of examining the body by striking with the finger or an instrument made for the purpose, to note the kind of sound elicited, p. 266.

Pericarditis, inflammation of pericardium, p. 238.

Pericardium (Gr. *peri*, about, and *kardia*, heart), the membranous investment of the heart, p. 219.

Perilymph Gr. *peri*, around, and *lympha*, water), the fluid within the bony labyrinth of the inner ear, p. 358.

Perinæum (Gr. *peri*, about, and *naiō*, to be situated), the part of the body between the genital organs in front and the opening of the bowel behind.

Periosteum (Gr. *peri*, about, and *osteon*, a bone), the outer lining membrane of bone, p. 17.

Periostitis, inflammation of periosteum, p. 25.

Peristaltic (Gr. *peristellō*, I involve), applied to the vermicular or worm-like movement of the bowel, p. 183.

Peritoneum (Gr. *peri*, about, *teinō*, I stretch), the delicate membrane investing the inner surface of the abdomen, p. 130.

Peritonitis, inflammation of peritoneum, p. 190.

Perityphlitis (Gr. *peri*, around, and *tuphlon*, the

head of the large bowel), inflammation of the connective tissue around the cæcum—the head of the large bowel, p. 163.

Pertussis (Lat. *per*, signifying excess, and *tussis*, a cough), whooping-cough.

Petechiæ (Italian, *petecchies*, flea-bites), small purple spots on the skin like flea-bites, p. 237, 240, 427.

Petrissage (French, meaning kneading), a term used in massage, p. 772.

Phalanges (plural of *phalanx*, Greek for a line of soldiers), applied to the bones of fingers and toes.

Pharynx (Gr.), the cavity at the upper end of the gullet, into which the mouth opens, p. 138.

Phlebitis (Gr. *phleps*, a vein, and *itis*), inflammation of veins, p. 246.

Phlyctenæ (Gr. *phluxein*, to be hot), applied to small vesicles on the eyeball, p. 369.

Phrenic (Gr. *phrēn*, the diaphragm), applied to the nerve and vessels of the diaphragm, p. 99.

Phthiriasis (Gr. *phtheir*, a louse), lousiness, p. 324.

Phthisis (Gr. *phthinomai*, I waste), consumption, p. 277.

Physiology (Gr. *phusis*, nature, and *logos*, a discourse), the science which treats of the functions of living things, p. 15.

Pisiform (Lat. *pisum*, a pea, and *forma*, shape), a bone of the wrist, p. 22.

Pityriasis (Gr. *pituron*, bran), a skin disease, accompanied by scurfiness, p. 319.

Plethora (Gr. *plēthō*, I fill), full-bloodedness, p. 235.

Pleura (Gr. *pleuron*, a rib), the membrane lining the inner surface of the chest walls and investing the lungs, p. 253.

Pleurisy, inflammation of the pleura, p. 266.

Pleuritis, same as pleurisy.

Pleuro-pneumonia (Gr. *pleura*, a rib, and *pneumōn*, the lung), an associated inflammation of lungs and pleura, p. 275.

Plexus (Lat., meaning a network), applied to a network of vessels or nerves, p. 99.

Pneumogastric (Gr. *pneumōn*, a lung, and *gastēr*, the belly), a nerve arising within the brain, and distributed to lungs, heart, stomach, &c., p. 96.

Pneumonia (Gr. *pneumōn*, the lung), inflammation of the lung), p. 274.

Pneumothorax (Gr. *pneuma*, air, *thōrax*, the chest), a collection of gas in the chest cavity, p. 269.

Podagra (Gr. *pous*, the foot, and *agra*, a seizure), gout, p. 432.

Polypus (Gr. *polus*, many, and *pous*, a foot), a variety of growth springing from a mucous membrane, p. 381.

Polyuria (Gr. *polus*, much, *ouron*, urine), applied to disease characterized by excess of urine, p. 302.

Pons Varolii (Lat. *pons*, a bridge, and *Varolius*, the name of an anatomist), a transverse mass of fibres connected with the cerebellum, p. 90.

Popliteal (Lat. *poples*, the ham), pertaining to the ham, p. 228.

Presbyopia (Gr. *presbus*, an old man, and *ōps*, the eye), impairment of power of accommodating the eye for near objects, common to age, p. 378.

Prognosis (Gr. *pro*, *gnōsis*, a knowing), the opinion as to the future course of a disease from a consideration of its nature, symptoms, &c., p. 13.

Prolapse (Lat. *pro*, forwards, and *lapsus*, a falling), a variety of displacement of an organ, p. 194.

Pronation (Lat. *pronus*, with face downward), the motion which turns the palm of the hand downward, p. 22.

Prophylactic (Gr. *pro*, before, and *phulassō*, I guard), employed in connection with the prevention of disease, p. 14.

Proteids (Gr. *prōtos*, first), applied to albuminous food-stuffs, p. 132.

Protoplasm (Gr. *prōtos*, first, and *plasma*, formed material), applied to the simplest form of living material, p. 15.

Pruritis (Lat., meaning an itching), a variety of perverted sensation, characterized by itching, pp. 323, 497.

Psoas (Gr. *psoa*), belonging to the loin, as psoas muscle, p, 73.

Psoriasis (Gr. *psoō*, I rub), a scaly disease of the skin, p. 877.

Pterygoid (Gr. *pterux*, a wing, and *eidos*, likeness), applied to bones of the head, and muscles connected with them, p. 70.

Ptomaines (Gr. *ptōma*, a dead body), active principles of the nature of alkaloids—derived from bodies in a state of decay, pp. 599, 1014.

Ptosis (Gr. *ptōsis*, a fall), a drooping of the eyelid, p. 369.

Ptyalism (Gr. *ptualon*, saliva), excessive secretion of saliva, p. 150.

Pubis (Lat. *pubis*, puberty), the front portion of the haunch-bone.

Puerperal (Lat. *puerpera*, a lying-in woman, from *puer*, a boy, and *pario*, I bear), pertaining to childbirth, p. 837.

Pulmonary (Lat. *pulmo*, a lung), belonging to the lung, p. 230.

Purgatives (Lat. *purgo*, I cleanse, and *ago*, I act), remedies which freely act upon the bowels, p. 855.

Purpura (Lat., meaning purple), a disease in which effusions of blood take place into the skin, p. 237.

Pus (Gr. *puon*, matter), matter produced in inflammation, p. 968.

Pyæmia (Gr. *puon*, pus, and *haima*, the blood), a condition of blood-poisoning, p. 236.

Pyelitis (Gr. *puelos*, a vessel, *itis*), an inflammation of a part of the kidney, p. 298.

Pylorus (Gr. *pulōros*, a gatekeeper), the part of the stomach where junction is made with the intestine, p. 130.

Pyrosis (Gr. *puroō*, I burn), waterbrash, p. 181.

Q.

Quartan (Lat. *quartus*, the fourth), a form of ague in which the attack returns after an intermission of two days, p. 428.

Quotidian (Lat. *quotidie*, daily), a form of ague in which the attack returns daily at the same hour, p. 428.

R.

Rabies (Lat. *rabies*, rage or madness), canine madness, p. 421.

Racemose (Lat. *racemus*, a cluster of grapes), applied to a form of gland structure, p. 137.

Radius (Lat. *radius*, a ray or spoke of a wheel), applied to the outer bone of the forearm, p. 22.

Ranula (Lat. *ranula*, diminutive of *rana*, a frog), a cystic tumour of the mouth, p. 150.

Rectum (Lat. *rectus*, straight), the straight part (the end) of the bowel, p. 130.

Rete mucosum (Lat. *rete*, a net), applied to the deep layer of the scarf-skin, p. 307.

Rubefacient (Lat. *rubrum*, red, and *facio*, I make), applications which redden the skin, p. 914.

Rubella (diminutive of *rubeola*), p. 402.

Rubeola (Lat. *ruber*, red), measles, p. 400.

S.

Saccharoses (Lat. *saccharum*, sugar), the chemical term applied to a variety of sugars, p. 587.

Sacral, related to *os sacrum*, which see.

Saphenous (Gr. *saphēnēs*, manifest), applied to a superficial vein and nerve of the leg, p. 229.

Sarcinæ (Lat. *sarcina*, a pack or bundle), a genus of microscopic fungi, so called from its appearance, p. 162.

Sarcolemma (Gr. *sarx*, flesh, and *lemma*, a skin), the connective tissue sheath of muscular fibres, p. 68.

Sarcous (Gr. *sarx*, flesh), applied to certain elements of muscular fibres, p. 68.

Sartorius (Lat. *sartor*, a tailor), applied to a muscle, p. 74.

Scabies (Lat. *scabies*, a scab), the itch, p. 323.

Scaphoid (Gr. *skaphē*, a skiff or boat, and *eidos*, shape), a bone of the foot, p. 22.

Scapula (Gr. *skapanē*, a spade), the shoulder-blade, p. 21.

Schneiderian, applied to the lining membrane of the nostrils, so called from Schneider, who first described it, p. 338.

Sciatic (Gr. *ischion*, the hip), applied to nerves, vessels, &c., p. 99.

Sciatica, neuralgia in the district of the sciatic nerve, p. 128.

Scirrhus (Gr. *skirros*, a hard tumour), a form of cancer, p. 434.

Sclerosis (Gr. *sklēros*, hard), a state of hardening of connective tissue, p. 118.

Sclerostoma (Gr. *sklēros*, hard, and *stoma*, the mouth), applied to a genus of parasitic worms, p. 175.

Scolex (Gr. *skōlēx*, a worm), a stage in the development of tapeworm, p. 168.

Scorbutus, scurvy, p. 237.

Scultetus, a form of bandage, p. 959.

Sebaceous (Lat. *sebum*, suet), applied to glands secreting an oily substance, connected with hair-sacs, p. 308.

Seborrhœa (Lat. *sebum*, fat, and Gr. *reō*, I flow), excess of fatty secretion of the skin, p. 327.

Sedatives (Lat. *sedo*, I ease), applied to soothing remedies, p. 897.

Septicæmia (Gr. *sēptikos*, putrid, and *haima*, the blood), blood-poisoning, p. 236.

Sequestrum (Lat. *sequestro*, I sever), a portion of dead bone, p. 26.

Serratus (Lat. *serra*, a saw), applied to a muscle, p. 71.

Serum (Lat. *serum*, akin to Gr. *oros*, whey), the fluid of blood, less its fibrinous element, p. 216.

Sigmoid (Gr. *sigma*, a letter of the Greek alphabet, and *eidos*, likeness), applied to a bend of the large bowel, p. 130.

Sinus (Lat. *sinus*, a hollow), a channel leading from an abscess to the surface, p. 261.

Soleus (Lat. *solea*, a sandal), applied to a muscle of the calf of the leg, p. 74.

Soporific (Lat. *sopor*, sleep, and *facio*, I make), remedies which induce sleep, p. 904.

Sordes (Lat. *sordes*, filth), crusts which form on lips and teeth in persons in exhaustion from disease, p. 519.

Spermatozoa (Gr. *sperma*, seed, and *zōon*, an animal), the active constituents in the male element in conception, p. 484.

Sphenoid (Gr. *sphēn*, a wedge, and *eidos*, shape), a bone of the cranium, p. 19.

Sphincter (Gr. *sphingō*, I bind), applied to circular muscles which close outlets, p. 130.

Spica (Lat. *spica*, an ear of corn), a variety of bandage so called from a supposed resemblance to the rows of an ear of corn, p. 958.

Spina bifida (Lat. *spina*, the spine, and *bifida*, cleft), a malformation of the spine, p. 457.

Spirillum (Lat. diminutive of *spira*, a curl), a variety of micro-organisms, p. 388.

Spirometer (Lat. *spiro*, I breathe, and Gr. *metron*, a measure), an instrument for measuring quantity of air expelled from the chest, p. 256.

Splanchnic (Gr. *splanchna*, the bowel), applied to nerves, &c., p. 99.

Sporadic (Gr. *speirō*, to scatter), applied to infectious disease occurring in scattered cases, not as an epidemic, p. 4.

Squamous (Lat. *squama*, a scale), scaly, p. 16.

Staphyloma (Gr. *staphulē*, a bunch of grapes), a protrusion of the coats of the eyeball, p. 372.

Stasis (Gr. *staō*, I stop), a local stagnation of blood, p. 248.

Sternum, Lat. for breast-bone, p. 21.

Stertorous (Lat. *sterto*, I snore), having a snoring sound, p. 11.

Stethoscope (Gr. *stēthos*, the breast, and *skopeō*, I examine), the instrument used for listening to the sounds of the heart and breathing, p. 266.

Strabismus (Gr. *strabōs*, twisted), squint, p. 376.

Strobilus (Gr. *strobilos*, a pine cone), applied to the adult tapeworm, p. 168.

Strophulus (Gr. *strophos*, a twisting of the bowels, colic), an eruption on the skin of infants, referred to derangement of bowels, p. 319.

Struma, same as scrofula, p. 431.

Styptics (Gr. *stuphō*, I constringe), remedies applied externally to stop bleeding, p. 919.

Subacute (Lat. *sub*, under, and *acutus*, sharp), applied to disease not quite severe enough to be called acute, p. 4.

Sublingual (Lat. *sub*, under, and *lingua*, the tongue), applied to glands, vessels, &c., situated beneath the tongue, p. 137.

Submaxillary (Lat. *sub*, under, and *maxilla*, the jaw), applied to glands and other structures lying under cover of the jaw-bone, p. 137.

Sucroses, a chemical term for a variety of sugars, p. 587.

Sudamina (Lat. *sudor*, sweat), minute vesicles produced in the skin by excessive sweating, p. 328.

Sudorifics (Lat. *sudor*, sweat, and *facio*, I make), remedies which increase sweating, p. 887.

Sudoriparous (Lat. *sudor*, sweat, and *pario*, I produce), applied to sweat glands, p. 307.

Supination (Lat. *supino*, to bend back), the motion by which the palm of the hand is directed upwards, p. 22.

Suppository (Lat. *suppono*, I place below), a conical mass of material containing some drug to be pushed up into the bowel, p. 1051.

Suppuration (Lat. *suppuro*, to generate matter), the formation of matter, p. 248.

Suture (Lat. *suo*, to sew), the junction of bones of the skull, p. 20; thread, wire, &c., by which wounds are closed, p. 970.

Symblepharon (Gr. *sun*, together, and *blepharon*, the eyelid), a condition in which the eyelids have become united, p. 369.

Symphysis (Gr. *sun*, with, and *phuō*, I grow), applied to a junction of bone, p. 22.

Syncope (Gr. *sunkopē*, a faint), fainting, pp. 243, 991.

Synechia (Gr. *sunechō*, I hold together), a disease of the eye in which the iris adheres to the cornea (anterior), or to the capsule of the crystalline lens (posterior), p. 372.

Synovia (Gr. *sun*, with, and *ōon*, an egg), a fluid poured out in joints, closed sacs, to lubricate the joint, &c., p. 23.

Synovitis (*synovia* [which see], and terminal *itis*), an inflammation of joints, p. 32.

Systole (Gr. *sustellō*, I contract), the contraction of the heart, p. 224.

T.

Tabes mesenterica (Lat. *tabes*, a consumption, and *mesenterica*, connected with the bowel), consumption of the bowel, p. 165.

Tæniæ (Gr. *tainia*, a ribbon), tapeworm, p. 168.

Talipes (Lat. *talus*, an ankle, and *pes*, a foot), club-foot, p. 82.

Tapotement (French, a *tapping*), a term in use in massage, p. 772.

Tarsus (Gr. *tarsos*, any broad flat surface), the ankle, p. 23.

Tenesmus (Gr. *teinō*, I stretch), straining at stool, p. 186.

Therapeutics (Gr. *therapeuō*, I nurse or cure), the branch of medical science dealing with the action of remedies in disease, p. 810.

Thermometer (Gr. *thermē*, heat, and *metron*, measure), an instrument for determining degree of heat, p. 9.

Thorax (Gr. *thorax*, a breastplate), the chest, p. 20.

Thrombosis (Gr. *thrombos*, a clot), clotting of blood in vessels during life, p. 246.

Thrombus (Gr. *thrombos*, a clot), the clot formed in a vessel during life, p. 216.

Thymus (Gr. *thumos*, thyme), applied to the thymus gland (p. 205), because it was compared to the flower of the plant by Galen.

Thyroid (Gr. *thureos*, a shield, and *eidos*, likeness), applied to a gland in the neck, p. 250.

Tibia (Lat. *tibia*, a pipe or flute), the large bone of the fore-leg, p. 23.

Tonsillitis, inflammation of tonsils; quinsy, p. 155.

Tonsils (Lat. *tonsilla*), glandular structures in the mouth, p. 136.

Tormina (Lat., meaning griping), griping pains in the bowels, p. 186.

Torticollis (Lat. *tortum*, twisted, and *collum*, the neck), wry-neck, p. 77.

Tourniquet (French *tourner*, to turn), instruments applied for the arrest of bleeding, p. 980.

Toxicology (Gr. *toxikon*, poison, and *logos*, a discourse), the branch of medical science which treats of poisons and their antidotes, p. 1014.

Tracheotomy (Lat. *trachea*, the windpipe, and Gr. *temnō*, I cut), the operation for opening the windpipe, p. 262.

Trapezium and **Trapezoid** (Gr. *trapezion*, a small table), bones of the wrist, p. 22.

Trapezius, applied to a muscle, p. 71.

Traumatic (Gr. *trauma*, a wound), produced by injury, as a traumatic inflammation, p. 54.

Trematode (Gr. *trēma*, a hole, a pore), a group of internal parasites, p. 168.

Triceps (Lat. *tres*, three, and *caput*, a head), applied to a muscle of the arm, p. 72.

Trichina (Gr. *thrix*, a hair), a minute nematode worm, parasitic, p. 175.

Trichinosis, the disease due to trichina, p. 175.

Trichocephalus (Gr. *thrix*, hair, and *kephalē*, the head), a genus of worms, a species of which is found in the human intestine, p. 175.

Tricuspid (Lat. *tres*, three, and *cuspis*, a point), applied to certain teeth, p. 220.

Tripolar (Lat. *tres*, three, and *polus*, an axis), applied to nerve-cells with three processes, p. 85.

Trochanters (Gr. *trochanter*, from *trochos*, anything round), prominences of the hip-bone, p. 23.

Tubercle (Lat. *tuberculum*, a little swelling), applied to certain small nodules of cells produced by morbid action in organs, p. 945.

Tuberculosis, the disease due to tubercle, p. 165.

Tympanites (same deriv. as below), distension of belly with gas.

Tympanum (Lat., meaning a drum), the drum of the ear, p. 356.

Typhlitis (Gr. *tuphlon*, the blind end of the large bowel, and *itis*, signifying inflammation), inflammation of the blind end of the large bowel, p. 163.

U.

Ulna (Gr. *ōlenē*, the elbow), the inner bone of the fore-arm, p. 22.

Umbilicus (Lat.), the navel, p. 131.

Unciform (Lat. *uncus*, a hook, and *forma*, shape), a bone of the wrist, p. 22.

Unipolar (Lat. *unus*, one, and *polus*, an axis), applied to nerve-cells with one process, p. 85.

Uræmia (Gr. *ouron*, urine, and *haima*, blood), a state of blood-poisoning. It occurs in disease of the kidney from retention in the blood of substances which ought to be expelled in the urine, p. 293, 296.

Urethritis, inflammation of the urethra (from Gr. *ouron*, urine), p. 988.

Urticaria (Lat. *urtica*, a nettle), nettlerash, p. 314.

Uterine, **Uterus** } (Lat. *uterus*, the womb), p. 479.

V.

Vaginitis, inflammation of the vaginal passage, p. 498.

Vagus (Lat., wandering), applied to a nerve from its wide distribution, p. 96.

Varicella (Lat., diminutive of *variola*, chicken-pox), p. 410.

Variola (Lat. *varius*, spotted), small-pox, p. 402.

Vascular (Lat. *vasculum*, a vessel), connected with or provided with vessels; applied to tissues containing blood-vessels, p. 835.

Vasomotor (Lat. *vasa*, vessels, and *motor*, a mover), applied to nerves controlling blood-vessels, p. 86, 233.

Venereal, applied to certain diseases connected with the sexual organs, p. 987.

Ventricles (Lat. *ventriculus*, diminutive of *venter*, the belly), a small cavity. V. of heart, p. 220, or brain, p. 91.

Vermicide (Lat. *vermis*, a worm, *cædo*, I kill), remedies which kill worms, p. 871.

Vermiform (Lat. *vermis*, a worm, and *forma*, shape), applied to a part of the large bowel, p. 130.

Vermifuge (Lat. *vermis*, a worm, and *fugo*, I drive out), remedies which expel worms, p. 871.

Vertebra (Lat. *vertebra*, a joint), applied to each of the bones forming the back-bone, p. 20.

Vertigo (Lat. *verto*, I turn), giddiness, p. 113.

Vesicant (Lat. *vesica*, a blister). Remedies which blister, p. 914.

Vibrio (Lat. *vibrio*, I shake), a variety of bacteria, p. 388.

Vomer (Lat. *vomer*, a ploughshare), the bone dividing the nasal cavity into two, p. 19.

Vulvitis, inflammation of the vulva, p. 498.

Z.

Zygoma (Gr. *zygon*, a yoke), a process of cheek-bone connecting it with the temple, p. 19.

Zymosis (Gr. *zymē*, ferment), an infectious disease, p. 4.

Zymotic, of the nature of zymosis, p. 4.

Begbie, Dr. Warburton, on scrofula, 876.
Belladonna, 888.
— actions and uses of, 899, *plate 10.*
— antidote to opium, 900.
— eserin antagonistic to, 903.
— pessaries, 511.
— poisoning by, 1016, 1027.
— preparations of, 899.
— stomach sedative, 855.
Bell-Coleman refrigerating machine, 633.
Bell-trap, 710.
Belly, dropsy of, 191.
— movements of, as a sign of disease, 11.
— muscles of the, 73, *pl. 2.*
— tumours of, 191.
Beltong, 630.
Benedictine, 668.
Bengal quince, 575, 868.
Benger's infant's food, 629.
— peptonized beef-jelly, 628.
Benjamin-tree, 881.
Benzoic acid, 881.
Benzoin, 881.
— compound tincture of, 919.
Berberis vulgaris, 576.
Bergeon, Dr., of Lyons, treatment of consumption, 827.
Bermuda arrow-root starch granules, 598.
Bermudas, health resorts, 803.
Bernard, Claude, experiment with foul air, 688.
— — on the liver, 147.
Bertholletia excelsa, 582.
Bertrich, bitter waters, 934.
Beta altissima and maritima, 571.
— vulgaris, 571, 588.
Betel-nut tree, 871.
Bethesda, lime waters, 946.
Beulah spa, near Norwood, 936.
Beverages for children, 451.
Bex for grape-cure, 952.
— mineral springs, 929.
Bhang, 902.
Biarritz, climate of, 785, 794.
Bicarbonate of soda, 819.
Biceps, 72.
Bichloride of mercury, 912.
Bicho, 983.
Bicuspid teeth, 136, 137.
Bicycling, 758.
Biffins, 575.

Bilberries, 576.
Bile, 129, 145, 147, 198.
— drugs which increase the flow of, 863, 868.
— in urine, 301.
— pigments, 147.
Bile-ducts, 141, 142.
— — inflammation of, 197.
Biliary colic, 199.
— disorders, waters for, 935, 936, 939.
Bilin, alkaline waters, 863, 937, 938.
Bilious fever, 411, *plate 6.*
— headache, 111.
— — euonymin for, 865.
Biliousness, 197.
Bilious remittent, 419, 429.
Bilirubin, 147.
Biliverdin, 147.
Bimeconate of morphia, 898.
Biniodide of mercury, 211.
Birch-tar, oil of, 882.
Birds' nests, edible, 546.
Birmensdorf, bitter waters, 934.
Birresborn, alkaline waters, 940.
Biscuits, 562.
Bismuth, preparations of, 854.
— uses of, 854.
Bites, poisonous, 980.
Bitter almonds, essence of, 581.
Bitter-apple, 574.
Bitter-cucumber, 574.
Bitter-sweet, 889, *plate 12.*
— — poisoning by, 1031.
Bitter tonics, 840.
— — prescriptions for, 1053.
— waters, 923, 933.
— — iron in, 948.
Black alder, 858.
Blackberries, 576.
Black death, 420.
— draught, 857.
— drop, 897, 1025.
— eye, 370, 975.
Blackpool, 789.
Black puddings, 545.
Black-root, 865.
Black sickness, 426.
— snake-root, a uterine stimulant, 893.
— vomit, 420.
— wash, 824, 917.
Bladder, the, 131, 293.
— affections of, in women, 511.
— — water in, 928, 936, 938, 939, 945, 947.
— — remedies for, 891, 892, 893.
— diseases of, 305.
— drugs which act on, 892.
— functions of, 294.
— inflammation of, 305.
— irritability of, 305.
— — henbane for, 900.
— paralysis of, 305.
— remedies which allay irritability of, 893.
— Rhus toxicodendron as tonic to, 889.
— to empty, 893.
Bladder-wrack, 584.
Blaeberries, 576.
Blaud's pill, 817, 823.
Bleaching-powders, 913.
Bleb, 313.
Bleeders, 238.
Bleeding, applications for, 835, 836, 867, 868, 872, 919.
— arrest of, 976, *plate 16.*
— arterial, 976, 977.
— at the navel, 458.
— capillary, 976, 977.
— control of, 835.
— from arm, arrest of, 978.
— from bowels, 166.
— from excessive exercise, 749.
— from hand, arrest of, 979.
— from head, arrest of, 979.
Bleeding from leg, arrest of, 979.
— from lungs, 282.
— from nose, 366, 465, 867, 980.
— from rectum, 193.
– from stomach, 161.
— gums, catechu for, 867.
— tendency to, 238.
— venous, 976, 977.
Blepharitis, 367.
Blighted ovum, 515.
Blind boil, 315.
— spot in the eye, 342.
Blindness, causes of, 378.
— partial, 378.
Blister, 916.
Bloemfontein, health resort, 800.
Blood, a drainage system, 2.
— a nourishing fluid, 2.
— changes in the lungs, 258.
— chemical constitution of, 216.
— circulation of the, 2, 230
— coagulation of, 215.
— diseases of the, 234.
— functions of the, 217.
— gases of the, 257.
— medicines acting on, 816, 818.
— pressure of the, 231.
— quantity of, 215.
— specific gravity of, 216.
— spitting of, 282.
— structure of the, 212.
— vomiting, 159.
— white-celled, 235.
— worms in the, 238.
Blood in the urine, 304.
Blood corpuscles of various animals, 214.
— glands, 204.
— poisoning, 236.
— — antipyrin for, 822.
— — eucalyptus for, 913.
— — from a wound, 203.
— tonics, 817.
— vessel tumours, 247.
— vessels, 140, 145, 225, *pl. 3.*
— — connected with the heart, 222.
— — distribution of the, 226, *plate 3.*
Bloodlessness, 234.
— waters for, 928, 935, 941.
Bloody flux, 185.
Blueberry-root, 893.
Blue-blindness, 379.
Blue cohosh, 893.
Blue-disease, 244, 286, 458.
Blue flag, 865.
— gum-tree, 883, 913.
— ointment, 824.
— pill, 824.
— rocket, 1027.
— stone, 869.
— — poisoning by, 1022.
— vitriol, poisoning by, 1022.
Blumenthal and Chollet's meat and vegetable tablets, 631.
Blush, inflammatory, 313.
Blushing, 233.
Boas, 985.
Bocklet, iron waters, 949, 950.
Body, chemical composition of, 534.
— exercises, 763.
— heat, loss of, 723.
Bog whortleberries, 576
Bohemian tea, 660.
Boil, 315.
Boiling, 607.
— point of water, 638.
Boils in the ear canal, 379.
— in genital region, 498.
"Bolting the food," 142.
Bombay for kidney diseases, 785.
Bonchurch, Isle of Wight, 785.
Bone, composition of, 17, 544.
— corpuscles or cells, 16*.
— disease, Barèges waters for, 944.
Bone diseases, lime or calcium for, 876.
— fractures of, 35–54.
— — temporary treatment of, 993–995.
— injuries of, 35.
— nutritive value of, 544.
Bones, classification of, 17.
— dislocation of, 54–67.
— of the arm: ulna, 22; radius, 22.
— of the chest or thorax, 21.
— of the cranium, 19.
— of the face, 19.
— of the foot, 23.
— of the hand, 22.
— of the leg, 23.
— structure and constitution of, 17.
Bones, abscess of, 26.
— diseases of, 25.
— inflammation of, 25.
— non-union of broken, 36.
— softening of, 31.
— tumours of, 31.
— union of broken, 36.
Boots, 731.
— for walking, 751.
— high heels for, 731.
— of children, 731.
Boracic acid, 911.
Borax, 819, 918.
Bore-tree, 577.
Boric acid, 911.
Bormio, thermal springs, 926.
Boroglyceride, 912.
Bothriocephalus latus, 168, 170.
Bourbonne-les-Bains, mineral springs, 929, 930.
Bourboule, 509.
Bournemouth, 785, 786, 790.
Bour-tree, 577.
Bouya, 567.
Bowel complaint, remedies for, 866.
— falling of, in children, 463.
— falling or prolapse of, 194.
— injections into the, 873.
— remedies for flatulence of, 871.
— remedies for worms in, 871.
Bowels, acidity of, magnesia for, 844.
— bleeding from, 166.
— cancer of, 167.
— consumption of, 165.
— derangement of, in children, 460.
— diseases of, 157.
— — mineral waters for, 925–947.
— drugs which act on, 855.
— foreign bodies in, 165.
— inflammation of, 162.
— massage for disorders of, 773.
— obstruction of, 164.
— stoppage of, 164.
— ulceration of, 164.
Bowenfels, health resort, 807.
Bower-Barff process, 711.
Bow-legs, 84.
Bozen, for grape-cure, 952.
Brachial artery, 227; — plexus, 99.
Brain, concussion and compression of blood-vessels of, 90, 104.
— congestion of the, 103, 247.
— development of the, 97.
— diseases and injuries of, 100, 128.
— dropsy of the, 102.
— effects of exercise on, 747.
— functions of the, 95*.
— inflammation of, 101.
— inflammation of membranes of, 100.
— membranes of, 90.
— softening of the, 102.
— special centres in the, 93*.
— structure of the, 88.
— weight and size of the human, 90, 91.
Brain and spinal cord, connections between, 93*.
Bramah closet, 718.
Brambles, 576.
Bran, 560; — bread, 562.

Brand's essence of beef, 628.
Brandy, 667.
Brank, 567.
Branks, 153.
Brassica, 914.
— campestris, 571.
— oleracea, 572.
Brayera anthelmintica, 872.
Brazilian holly, 659.
Brazil-nuts, 582.
Bread, 561, 562.
— adulteration of, 597.
Bread-fruit, 578, 579.
Break-bone fever, 414.
Breakfast, samples of a, 623.
Breast, affections of the, 516.
— bandage for, 958.
— gathered, 516.
Breast-bone, 21.
— — fracture of, 48.
Breasts, in pregnancy, 490.
— swelling of, in infants, 459.
Breath, effects of exercise on the, 745.
Breathing, apparatus of, 250.
— as a sign of disease, 11.
— difficulty of, 261, 284.
— disturbances of, 512.
— movements of, 254.
— nervous control of, 256.
— purpose of, 257.
— stertorous, 11.
— varieties of, 255.
Breathlessness, as a sign of disease, 11.
Bridge of Allan, 785, 789.
Brighton, 787.
Bright's disease (see also *Kidney Disease*), 295.
— — Bethesda waters in, 946.
Brisbane, climate of, 806.
Bristol, hot wells, 928.
British brandy, 570.
— health resorts, 785.
Broad tape-worm, 170.
Broca, M., on paralysis, 120.
Broccoli, 572.
Broiling, 608.
Bromal hydrate, 905.
Bromide of potassium, 818, 905.
Bromides, 905.
Bromism, 905.
Bromo-iodine waters, 923.
Bronchial affections, waters for, 936, 944, 947.
— arteries, 228.
— tubes, 251.
— tubes, stimulants to secretion from, 879.
Bronchiectasis, 272.
Bronchitis, 270.
— and throat affections, climates for, 784.
— baths in, 742.
— chronic, 271.
— climate for, 78
— in children, 460.
— inhalations for, 883.
— remedies for, 880, 882, 883, 885, 886, 889, 893, 911, 913.
Bronchocele, 210.
Bronchus, 251.
Bronzing of the skin, 212.
Brood capsules, 172.
Broom-tops, 891.
Brose, 564.
Brow ague, 112.
Brown-Séquard and animal extracts, 955*.
Browne, Dr. Crichton, on effects of exercise on the nervous system, 746.
Brucia, 840.
Brucine, 896.
Brückman, iron waters, 949.
Bruises, in children, 465.
— treatment of, 974, 975.
Brünner's glands, 140.

Brussels sprouts, 572.
Bryony, 574.
Bubo, 987, 988.
Buboes in plague, 420.
Buchan, Dr., on climate, 789, 790.
Buchan's ventilating trap, 709.
Buchu, preparations of, 891.
Buckskin as clothing, 727.
Buckthorn, alder, 858.
— common, 858.
— preparations of, 858.
— uses of, 858.
Buckwheat, 567.
— composition of, 558.
Bude, 788.
Budrum, 564.
Buffalo, lithia waters, 943, 946.
Buffon, French naturalist, 385.
Bugs, 325.
Builth, sulphur waters, 943.
Buja, 868.
Bulimia, 146.
Bulla, 313.
Bungarus, 985.
Bunions, 78.
Burdock, 889.
Burgundy, 676.
Burnett's disinfecting fluid, 914.
Burns, 997.
— from chemicals, 1002.
— from explosion, 1001.
— in children, 465.
— of eyeball and lids, 1002.
— of the eye, 857.
— of the eyelid, 369.
— treatment of, 999.
Burnt sponge, 211.
Bursæ, diseases of, 77.
— structure and functions of, 67.
— synovial, 75.
Burtscheid, sulphur waters, 943, 944.
Bussang, iron waters, 949.
Butcher's meat, chemical analyses of, 542, 543.
Butler's vermin-killer, 1028.
Butter, 542, 550, 556.
— composition of, 556.
Butterine, 542, 557.
Butter-milk, composition of, 552.
Butter-nut, 581, 865.
Butyl chloral hydrate, 905.
Butyric acid, 557.
— ethers, 667.
Butyrin, 557.
Buxton, thermal springs, 926.

C.

Cabbage, composition of, 572.
Cachexia, 4.
— cancerous, 435.
Cæcum, 130, 140.
— inflammation of walls of, 163.
Caffea arabica, 660.
Caffeic acid, 655.
Caffein, 654, 896.
Caffeo-tannic acid, 655.
Cagliari paste, 563.
Cagniard de Latour, 354.
Cajuput, preparations of, 849.
Calabar bean, 902.
— — poisoning by, 1028.
— — preparations of, 902.
Calcaneus, 83.
Calcareous degeneration, 243.
— waters, 923.
Calcium in human body, 534.
— sulphide of, 876.
Calculus, 298, 1064.
Calf-knee, 83.
Calidarium, 736.
California, health resort, 800.
Callus, 36.
Calmia latifolia, 545.
Calomel, 824.
— pill, 824.
Calorie, 529.
Calorimeter, 530.
Calumba, preparations of, 840.
— root, 840.
Calves' liver, 544.
Camembert cheese, 555.
Camera, photographic, 343.
Camphor, 850, 881.
— actions and uses of, 831, 850.
— liniment, compound, 917.
— poisoning by, 1029.
— preparations of, 831, 850.
Camphora officinarum, 850.
Camphorated chloral, 905.
Canaliculi, 18.
Canals, semicircular, of ear, 357.
Canary Islands, 784, 797.
Cancellated bone, 17.
Cancer, 433.
— in bones, 31.
— in genital region, 500.
— in lungs, 284.
— in the skin, 322.
— of bowels, 167.
— of kidneys, 300.
— of lip, 150.
— of liver, 200.
— of stomach, 160.
— of womb, 503.
Cancerous cachexia, 435.
Canella alba, 595.
Cane-sugar, 537, 542, 587.
Canine tooth, 136, 137, 451.
Canities, 329.
Cannaben, 902.
Cannabin, 902.
Cannabis Indica, poisoning by, 1028.
— sativa, 902.
Canna edulis, 586.
Cannes, 790, 793.
Cannet, 793.
Canstatt, mineral springs, 929.
Cantharides, poisoning by, 1016, 1029.
Cantharidin, 916.
Cantharis vesicatoria, 916.
Cape, the, as health resort, 783, 785.
Capeline bandage, 960, 963, *plate 15*.
Capers, 595.
Capetown, health resort, 800.
Capillaries, circulation in, 232.
— structure of, 225.
Capillary bleeding, 976, 977.
— bronchitis, 271.
Capon, 545.
Capparis spinosa, 595.
Caproin, 557.
Caprylin, 557.
Caps, woollen, 730.
Capsicum annuum, 593.
Caramel, 589.
Caraway, 594.
— preparations of, 849.
Carbo-hydrates, 133.
— in human body, 536.
— use of, 541.
Carbolic acid, 910.
— — inhalation, 883.
— — poisoning by, 1016, 1018.
— — preparations of, 910.
— — stomach sedative, 855.
— — varieties of, 910.
Carbon in human body, 534.
— tetrachloride of, 909.
Carbonaceous food-stuffs, 538, 542.
Carbonate of lime in human body, 535.
— — in water, 639.
— of sodium in human body, 535.
Carbonic acid gas in air, 683.
— — — in blood, 217, 257.

Carbonic acid gas in water, 638, 640.
— — — produced by breathing, 687.
— — — produced by fermentation, 665.
— — — production of, 651.
Carbuncle, 315, 393.
Carcinoma, 433.
Cardamoms, 594.
— preparations of, 849, 850.
Cardiac, 1064.
Cardoon, 573.
Carica papaya, 848.
Caries, 26.
Carlowitz, 676.
Carlsbad bitter waters, 933, 934.
Carminatives, 839, 848.
Carnrick's beef peptonoids, 629.
— infants' food, 629.
Carotid arteries, 227.
Carpets, arsenic in, 732.
Carpus or wrist, 22.
Carrageen-moss, 584.
— — composition of, 584.
Carriage of injured persons, 996, *pl. 14.*
Carron-oil for burns, 844.
Carrots, 571.
— composition of, 569.
Cartilage, kinds of, 16*, 23.
Cartilages of knee-joint, displacement of, 66.
Cartilaginous tumour, 31.
Carum Carui, preparations of, 849.
— — uses of, 594.
Carya alba, 581.
— olivæformis, 581.
Cascara Sagrada, 858.
Cascarilla, 840.
Casein, 132, 144, 536, 550.
Caseous, 1065.
Cashew-nuts, 582.
Cassava, 542.
— bread, 586.
Cassia, 595.
Castanea vesca, 582.
Castor-oil, 856.
— — seeds, poisoning by, 1029.
Catalepsy, 521.
Cataract, 374.
— at birth, 458.
Catarrh, 154.
— acute gastric, 158.
— baths in, 739.
— chronic, 163.
— — Plombières waters for, 927.
— intestinal, 162.
— laryngeal, climate for, 784.
— of bile-ducts, 197.
— of throat, mountain climates for, 795.
— opium for, 899.
Catechu, 867.
— black, 867.
— lotion, 918.
— preparations of, 867.
— uses of, 867.
Cathartic, the term, 856.
Cathartics, list of, 860.
Catheter, 1050, 1065.
Cauda equina, 92.
Cauliflower, composition of, 572.
Caulophyllum, 893.
Caustic alkalies, poisoning by, 1019.
— ammonia, poisoning by, 1016.
— lime, poisoning by, 1016.
— lunar, 870.
— — poisoning by, 1020.
— potash, poisoning by, 1016.
— soda, poisoning by, 1016.
Cauterets, sulphur waters, 943, 944.
Cavendish, Hon. Henry, discovery of composition of water, 635.
Caviare, 548.
Cayenne, 593.
— preparations of, 849.
Cedar Keys, health resort, 803.
Celery, 572, 573.
Cell theory, 16.
Cells, structure, size, form, varieties, functions of, 15.
— wander, 214, 248.
Cellular tissue, 16*.
Cellulose, 537.
Celsius scale, 779.
Cement of teeth, 137.
Centigrade scale, 779.
Centipede sting, 984.
Central canal of spinal cord, 92.
Central nervous system, functions of, 93.
Cephaëlis Ipecacuanha, 852.
Cephalalgia, 111, 1065.
Cephalic vein, 229.
Cerastes cornutus, 985.
Cereals or grains, percentage composition of, 558.
Cerebellum, 88, 89, 96*.
Cerebral hemispheres, 88, 95*.
— nerves, 97*.
— peduncles, 89, 96*.
Cerebrin, 537.
Cerebrinin for sleeplessness, 955*.
Cerebritis, 101.
Cerebro-spinal fever, 426.
— — fluid, 91.
— — system, 87.
Cerebrum, 88.
Cerium, oxalate of, 855.
Cerumen or ear-wax, 356.
Cervical nerves, 91, 92, 99; — plexus, 99.
— vertebræ, 20, 88.
Cesspools, 705.
Cestodes or tæniæ, 167, 168.
Cetraria islandica, 384.
Cevadilla, poisoning by, 1030.
Ceylon cardamoms, 594.
— moss, 584.
Chain-viper, 985.
Chalazion, 368.
Chalk, 844.
— in water, 639.
— preparations of, 844.
— stones, 432.
Chalky waters, 923.
Challes, sulphur waters, 942, 943.
Chalybeate springs, 923, 947, 949.
Chambers of the eye, 340.
— of the heart, 220.
Chamois, porosity of, 727.
Chamomile flowers, 840.
— — infusion of, an emetic, 851.
Champagne, 676.
Chancre, hard, 423.
— soft, 987.
Chancroid, 423.
Change of life, 480, 482.
Channel Islands, the, 787.
Charas, 902.
Charlton, health resort, 807.
Charqui, 630.
Chartreuse, 668.
Chateldon, lime waters, 946.
Chaudes Aigues, hot spring, 937.
Chaumont, De, 688, 689, 697.
Cheddar cheese, 554.
Cheek-bones, 19.
Cheese, composition of, 554.
Cheese-maggot, 555.
Cheese-mite, 555.
Chelonia mydas, 549.
Cheltenham, iron waters, 949.
— mineral springs, 929, 930.
— Pitville water, 934, 935.
Chemical composition of the body, 534.
— compounds found in human body, 535.
— elements in the body, 534.
— food in scrofula, 432.
Chemicals, burns from, 1002.
Chenopodium Quinoa, 567.
Cherries, 574, 575, 576.
Cherry laurel water and oil, 1027.
Cherry Rocks spring, Kingswood, 936.
Chervil, 594.
Chest, 138.
— affections, burdock for, 889.
— bandage for, 959.
— cold in, 155.
— dropsy of the, 267.
— examination of the, 265.
— muscles of the, 71.
— the, in diagnosis, 12.
— triangular bandage for, 962.
Chestnut, 582.
Chestnuts, composition of, 580.
Chicken-pox, 410, *plate* 7.
— tea, artificial digestion of, 847.
Chick pea, 567.
Chicory, 661.
Chigoe, 983.
Chilblains, 1007.
— iodine for, 916.
Child-bed fever, 518.
Child-birth, convulsions after, 517.
— diseases after, 516.
Child-crowing, 273, 464.
— — bromide of potassium for, 905.
Childhood, diseases common to, 459.
Children, bathing for, 452.
— beverages for, 451.
— clothing for, 452, 730.
— exercise for, 453, 752.
— food for, 449, 617.
— management of, in disease, 453.
— management of, in health, 437.
— period and rate of growth in, 466.
— premature, 448.
— signs of disease in, 453.
— teething in, 451.
Children's apartments, 453.
— boots, 731.
— diseases, 457-465.
— sea-bathing for, 739.
Chilian pine, 582.
Chimaphila umbellata, 892.
Chimney, ventilation by, 698.
Chimney-sweeper's cancer, 323.
China, sea-voyage to, for lung affections, 783.
Chin bandage, 959.
Chinese moss, 584.
Chique, 983.
Chiretta, 841.
Chittem-bark, 858.
Chives, 595.
Chloasma, 322.
Chloralamid, 906.
Chloral hydrate, 904.
— — antidote to strychnine, 905.
— — poisoning by, 1016, 1026.
Chloric ether, 906.
— — prescriptions, 1058.
Chloride of ammonium in body, 535.
— of magnesium in human body, 535.
— of potassium in human body, 535.
— of sodium, 819.
— — in human body, 535.
— — in water, 640.
Chlorinated lime, 876, 913.
Chlorine gas, 913.
— in human body, 534.
Chlorobrom, 906.
Chlorodyne poisoning, 1026.
Chloroform, actions and preparations of, 906.
— death by, 907.
— gastric sedative, 855.
— poisoning by, 1016.
Chlorophyll, 582.
Chlorosis, 235.
— waters for, 944, 948, 950.
Chocolate, 662.
Choking, 157, 1011.
— in children, 465.
Cholagogues, 856.
Cholera, 185, 186.

Cholera bacillus, 393.
— camphor for, 850.
— English, 184.
— infantile, 462.
Cholestrin, 147.
Chondodendron tomentosum, 891.
Chondrin, 132, 536.
Chondrus crispus, 584.
Chordæ tendineæ, 222.
Chordee, 988.
Chorea, 125.
Choroid coat, the, 340.
— — diseases of, 375.
Chrisma, 918.
— sulphur, 826.
Christchurch, climate of, 806, 808.
Christison, Sir Robert, on coca, 663.
Chronic bronchitis, 271.
— — climate for, 784, 787, 789, 792, 794, 795, 797, 799, 807.
— — mineral waters for, 938, 944.
— — remedies for, 833, 840, 843, 880, 881, 882, 911.
Chronic catarrh of stomach, 158.
— drinking, hydrastis for, 865.
— gastric catarrh, 158.
— gastritis, 158.
— inflammation of bladder, 305, 881.
— — of stomach, 158.
— pneumonia, 276.
— rheumatic inflammation, 33.
Chrysophanic acid ointment, 918.
Chrzonszczewsky's experiment, 141.
Churrus, 902.
Chyle, 145, 200.
Chyluria, 238, 305.
Chyme, 129, 143, 145.
Cicatrix, 313, 968.
— of burns, 998.
Cicer arietinum, 567.
Cichorium Endivia, 573.
— Intybus, 661.
Cicuta virosa, poisoning by, 1030.
Cider, 575, 677.
Cilia of cells, 15*.
Ciliary muscle of eye, 340.
— processes, 340.
Cimex lectularis, 325, 984.
Cimicifuga racemosa, 893.
Cinchona Calisaya, succirubra, Condaminea, 820.
Cinchonine, 820.
Cinnamomum, 595.
— Camphora, 831.
Cinnamon, 595, 850.
— preparations of, 849.
Circulation, apparatus of the, 218.
— effects of exercise on, 745.
— in arteries, 231.
— in lungs, remedies which lessen, 883.
— in the capillaries, 232.
— in veins, 232.
— nervous control of, 233.
— of the blood, 2.
— of the blood, description of, 230.
— rapidity of, 233.
— systemic, 230.
Circumduction, 25.
Cirrhosis, 276.
— of liver, 196.
Cissampelos abutua, 891.
Cistern for water-closet, 718.
Cisterns, 719.
Citric acid, 574.
Citrin ointment, 824, 917.
Citron, 577.
Citrullus colocynthis, 860.
— vulgaris, 574.
Citrus acida, 577.
— Aurantium, 577.
— decumana, 577.
— japonica, 577.
— limetta, 577.
Citrus limonum, 577.
— medica, 577.
— pompelmoos, 577.
Cives, or Chives, 595.
Cladonia rangiferina, 584.
Claret, 676.
Clark, Sir James, on climate, 786, 787, 788.
Clark's process to soften water, 639.
Clasp-bone, dislocation of, 66.
Clavicle or collar-bone, 21.
Cleft-palate, 149, 457.
Clergyman's sore throat, 287.
— — — Eaux Bonnes waters for, 944.
Clifton, springs, 927.
Climate, 775.
— affected by air moisture, 779.
— affected by temperature, 775.
— and rainfall, 780.
— for asthma, 784, 787, 789, 794, 795, 800, 807.
— for convalescents (see *Convalescence*).
— for digestive troubles, 796.
— for diseases of the general system, 785, 803.
— for gout, 788, 799.
— for heart affections, 785.
— for kidney diseases, 785, 798, 799, 801.
— for lung affections, 782, 783, 787, 792, 794, 798, 803.
— for malaria, 785, 800, 804, 807.
— for nervous diseases, 785, 794, 803.
— for rheumatism, 788, 795, 799.
— for scrofula, 785, 786, 789, 791, 793, 794.
— influenced by water, 775.
— suitable for diseases of air-passages, 782, 786, 794, 795, 797, 798, 799, 800, 807.
— variation in diet according to, 620.
Climates for consumption of the lungs (see under *Consumption*).
Climates for diseases of abdominal organs, 785, 801.
Climbing, energy expended in, 751.
Clonic spasm, 126.
Closet, Bramah, 718.
— hopper, 717.
— pan, 717; — valve, 718.
— wash-out, 717.
Clot, 68.
Clothing, absorption by, 732.
— as a conductor of heat, 724.
— contagion in, 732.
— during pregnancy, 490.
— for children, 452.
— for summer, 724, 728.
— for winter, 723, 728.
— impermeable to moisture, 727.
— inflammability of, 729.
— material for, 728.
— of infants, 444.
— on fire, to extinguish, 998*.
— poisonous dyes in, 732, 1032.
— qualities of suitable, 724.
— shape and form of, 729.
— suggestions as to healthy, 475.
Clotho arietans, 985.
Clove-hitch, 964.
Cloves, 595, 849.
— preparations of, 849.
Clubbed hands, 84.
Clysters, 873.
Coagulation of blood, 215.
Coaptation of bone, 38
Coarse sharps, 560.
Cobbold, Dr., on tape-worm, 173.
Cob-nuts, 581.
Cobra-di-capello, 985.
Coca or cuca, 663, 904.
Cocaine, 663, 904; — gastric sedative, 855.
— preparations of, 904.
Coccinella, nervous system of, 95.
Cocculus palmatus, 840.
— Indicus, poisoning by, 1030.
Coccyx, 20, 22.
— nerves, 92, 99.
Cochineal-red, arsenic in, 732.
Cochlea, 358.
Cochlearia armoracia, 572.
Cocoa, 661.
— adulteration of, 662.
— Brazilian, 663.
— composition of, 662.
— value of, 662.
Cocoa-nibs, 662.
Cocoa-nut, 580.
Cocos nucifera, 581.
Codeia, 897, 898.
— preparations of, 898.
Cod-fish, 547.
Cod-liver oil, 877.
— — — a blood tonic, 877.
— — — in cold climates, 621.
— — — in consumption, 281.
— — — in scrofula, 432.
Cœlenterata, nervous structure in, 93.
Cœliac axis, the, 228.
Coffee, 660; — action of, 661.
— composition of, 660.
"Coffee grounds," 160, 161.
— leaves, 661.
Coghill inhaler, 883, *plate 19*.
Cognac, 667.
Cohran, Dr., on education, 479.
Colchicum, action and uses of, 828.
— a poison, 1016, 1031.
— preparations of, 828.
Cold, effects of, 1005.
— — in children, 459.
— in stomach, 158.
— in the chest, 155.
— in the eye, 368.
— in the head, 154, 364.
— — remedies for, 850, 854, 887, 912, 914.
Cold bath, temperature of, 734.
— baths in fever, 734.
— water, effects of drinking, 921.
Coleman, J. J., Glasgow, on preservation of food by cold, 633, 634.
Colewort, 572.
Colic, 182.
— biliary, 199.
— in children, 461.
— lead, 1022.
Colica Pictonum, 1022.
Collapse, 990.
— in cholera, 188.
— of the lungs, 283.
Collar-bone, 21.
— — dislocation of, 57.
— — fracture of, 40.
— — temporary treatment of fracture of, 993.
Colleges for women, 478.
Collidine, 901.
Colloid, 1065.
Colocynth, 574.
— poisoning by, 1029.
— preparations and uses of, 860.
Colocynthin, 860.
Colon, 130, 140.
Colorado springs for consumption, 801.
Colostrum, 439.
Colour, 351; — blindness, 379.
— of skin in diagnosis, 9.
— perception of, 352.
Colours, complementary, 351.
— fundamental, 351.
Colt's-foot, 886.
Columnæ carneæ, 222.
Columnar epithelium, 139.
Columns in spinal cord, 92, 92*.
Coma, 102, 103.
Combustion, 527.
Comedones, 327.

Comma bacillus, 393.
— — in cholera, 187.
Comminuted fractures, 35.
Commisural fibres, 95.
Commissure, optic, 89.
— salt, in water, 640.
— — waters, 923.
— — — iron in, 947.
— sewers, 704.
Complementary colours, 351.
Compound fractures, 35, 38.
Conception, 483.
Concussion of brain, 103.
— of spine, 118.
Condensed milk, composition of, 553.
Condillac, lime waters, 946.
Condiments, 591.
Conduction of heat, 699.
Condyles, 22, 23.
— splitting of the, 43.
Condy's fluid, disinfectant, 912.
— — purification of water by, 650.
Cones of eye, 341.
Confection of sulphur, 826.
Congenital, 54, 1065.
Congestion, 247.
— of the brain, kidney, liver, lungs, &c. See *Brain*, *Liver*, *Lungs*, *Kidney*, &c.
Congestive disorders, salt waters for, 928.
Conium maculatum, 885, 903, *plate 11*.
— poisoning by, 1016, 1030.
Conjunctiva, the, 339.
Conjunctivitis, 339, 368.
— bichloride of mercury wash in, 368.
Connective tissues, 15*.
Consciousness, 98.
— double, 116.
— drugs which destroy, 906.
Consonants, 264.
Constant current, 952.
Constipation, 163, 183.
— as cause of headache, 111.
— baths for, 741.
— Cascara Sagrada in, 184.
— habitual, remedies for, 858, 859, 860.
— in pregnancy, 512.
— remedies for, 855-865.
— waters for, 925, 933.
Consumption, 277, 431.
— night sweats of, remedies for, 888, 900.
— of bowels, 165.
— of the lungs, climates for, 281, 783, 785, 794, 795, 799, 800, 803, 807.
— remedies for, 281, 823, 827, 877, 882, 883, 913.
— waters for, 938, 942, 944, 945, 947.
Consumptive cough, prussic acid for, 855.
Contact, sense of, 335.
Contagia, 8.
Contagion, 384.
— in clothing, 732.
Continental health resorts, 792, 794.
Contracted muscles or tendons, 82.
Contrexéville, lime waters, 946.
Contused wounds, 966.
Contusions, 974.
Convalescence, climates in, 785, 786, 789, 791, 795.
— waters in, 925, 928, 948.
Convallamarin, 833.
Convallaria majalis, 833.
Convection of heat, 699.
Convex lens, effect of, 344.
Convolutions of the brain, 88, 89.
Convolvulin, 861.
Convolvulus scammonia, 861.
Convulsions, 122.
— in children, 463.
— in pregnancy or after childbirth, 517.
— remedies for, 517, 850, 905.
Cooking, loss in, 610.
— principles of, 605.

n

Coonoor, Indian health resort, 804.

Eye surgery, electricity in, 953.
Eye-tooth, 136.

F.

Face, fracture of bones of, 39.
— pimples, 328.
Fachingen alkaline waters, 937.
Facial breathing, 256.
— nerve, 89, 98*.
— palsy, 98*, 120.
Fæces, 12, 1067.
Fahrenheit's scale, 779.
Fainting, 243, 990.
— remedies for, 843, 850.
Falkenstein, near Soden, 932.
Falling of bowel in children, 463.
— of womb, 505.
— sickness, 123.
Fallopian tubes, 480.
Falls on the head, in children, 465.
Falmouth, 787.
False croup, 464.
— measles, 402.
— or floating ribs, 21.
— teeth, 157.
Famine fever, 419.
Fangs of teeth, 136.
Faradic current, 952.
Farcy, 422.
Farinaceous foods, 584.
Farr, Dr. Wm., on children's mortality, 437.
Fascia, 67.
Fat beef, 543.
— chemical composition of, 532.
— cells, 16; — cure, 626.
— mutton, 543.
— pork, 543.
Fats, use of, 540.
— in human body, 536.
Fatty degeneration, alcoholic, 199, 671.
Fatty tissue, 16*.
— — of heart, 242.
— — of liver, 199.
Fauces, 136.
— diseases of, 154.
Favus, 326, *pl. 4.*
Fayrer, Sir Joseph, on India, 805.
— — on snake-bite, 986.
Febrifuge medicines, 820.
Feeding, artificial, 441.
Feet, covering for the, 730.
Fellathal, alkaline waters, 937.
Female generative organs, 479.
Femoral artery, 228.
— hernia, 192.
— vein, 230.
Femur, or thigh-bone, 23.
Fenestra rotunda and ovalis, 356.
Fennel, 594.
— preparations of, 849.
Fermentation, 666.
— in baking, 561.
Fermentative changes in stomach, carbolic acid for, 911.
Ferrier, Dr., brain experiments, 98, 94*.
Ferrier's snuff, 155, 854.
Ferula Galbaniflua, 881.
Fever, general treatment of, 398.
— bath, 924.
— bilious, 411, *plate 6.*
— cerebro-spinal, 426.
— child-bed, 518.
— continued, 393.
— dandy, 414.
— enteric, 411, *plate 6.*
— famine, 419.
— gastric, 411, *plate 6.*
— intermittent, 427.
— intestinal, 411, *plate 6.*
— jungle, 429.
— marsh, 427.
— milk, 516.
— mixtures, 416, 419, 1057.
— puerperal, 236, 518.
— relapsing, 419.
— remedies for, 822, 834, 887, 891.
— remittent, 429.
— rheumatic, 429.
— scarlet, 399, *plate 6.*
— seven-day, 419.
— spotted, 426.
— three-day, 414.
— traumatic, 991.
— typhoid, 411, *plate 6.*
— typhus, 410, *plate 6.*
— well, 924.
— yellow, 420.
Feverish colds, ammonia for, 887.
Fevers attended by rash, table of, 399.
— infectious, with rash, 397.
— — without rash, 415.
— non-infectious, 427.
Fibres, nerve-, 85, 91*.
Fibrillæ, 18.
Fibrin, 215, 536. Fibrinogen, 216.
Fibrinoplastic substance, 216.
Fibro-cartilage, 16*, 24.
Fibroid or fibrous tumour, 31, 503.
— phthisis, 276.
Fibrous tissues, 16*.
Fibula, or clasp-bone, 23.

Fick's experiment, 539.
Ficus, varieties of, 578.
Field-beet, 576.
Field's flushing-tank, 717.
Fife, coast of, for scrofula, 785.
Figs, composition of, 578.
Filaria medinensis, 984.
— sanguinis hominis, 238, 320.
Filbert-nuts, 581.
Filippi, Italian naturalist, 391.
Filters for domestic use, 648.
Fine sharps, 560.
Finger, bandage for, 957.
Fingers, dislocation of, 61.
— fracture of bones of, 46.
— muscles of, 72, 73.
— supernumerary, 84.
Fire in the eye, 373.
Fire-proof starch, 729.
"First Aid," 1034.
— — in accidents by fire, 997*.
First intention, healing by, 968.
Fish, composition of, 542, 547.
Fish-skin disease, 320.
Fission, 387.
Fissure of brain, great longitudinal, 89.
— of Sylvius, 89.
Fistula, 500.
— in anus, 194.
— of tear-sac, 370.
Flannel, porosity of, 727.
Flat-foot, 83.
Flatulence, 111.
— in children, 461.
— of the bowel, remedies for, 871.
— of stomach, remedies for, 848.
— remedies for, 850, 872, 913.
Flavour, sense of, 337.
Flax and linen as conductors of heat, 724.
Flea, common, 325.
Flesh-mole in pregnancy, 515.
Flesh-worm, 175.
Flexion, movements of, 25.
Flexors (muscles), 72, 75.
Flinsberg, iron waters, 949.
Flooding, 515.
Florida, a health resort, 802.
Flour, 542, 560.
— adulteration of, 597.
Flowers of sulphur, 826.
Fluctuation in joints, 32.
Fluid beef, Johnston's, 628.
— — Savory and Moore's, 628.
Flummery, 564.
Fluoride of calcium in human body, 535.
Fluorine in human body, 534.
Flushing drains, 716.
— tank, Field's, 717.
— water, 718.
Fœniculum dulce, 849.
— vulgare, 594.
Fœtus, 485.
Foie gras, 544.
Folkestone, 785, 788.
Fomentations, 1050.
Food, 2, 131.
— artificial digestion of, 847.
— business of, in body, 534, 538.
— composition of, 542, *plate 9*.
— destination of, 134.
— digestibility of, 600.
— during pregnancy, 489.
— for children, 449, 617.
— Murdoch's liquid, 628.
— poisonous, 1032.
— preservation of, 630.
Foods, 525.
— adulteration of, 597.
— carbonaceous, 542.
— classification of, 538.
— for infants, 442.
— nitrogenous, vegetable, 558.
Foods, non-nitrogenous, animal, 556.
— non-nitrogenous, vegetable, 584.
— quantity digested, 604.
Food-stuffs in the body, uses of, 541.
Fool's parsley, 903, *plate 11*.
— — poisoning by, 1030.
Foot, the, 23, *pl. 1*.
— dislocations of, 66.
— fracture of bones of, 53.
— muscles of, 74.
Foot and leg, bandage for, 957.
— triangular bandage for, 963.
Football exercise, 759.
Foot-pound, 529.
Foot-sweat, stinking, 328.
Forbidden fruit, 577.
Forceps, artery, 980.
Forearm, 22.
— fractures of, 43, 44.
— muscles of, 72.
Forests, temperature in, 776.
Form, as a sign of disease, 9.
Foul sores, remedies for, 843, 912.
Four-handed seat, 996.
Four-tailed bandage, 959.
Fousel oil, 664.
Fowler's solution of arsenic, 822.
Fracture, dislocation, and bruise, distinction between, 34.
Fractures of bone, 35.
— temporary treatment of, 993, *pl. 15*.
Fragaria vesca, 576.
Franco-Swiss Co. milk food, 629.
Frangula bark, extract of, 858.
Frankland, Professor, 531.
Franzensbad, bitter waters, 934, 935.
— iron waters, 949.
Fraser, Prof., on strophanthus, 833.
Fraxinus ornus, 590.
— rotundifolia, 590.
Freckles, 322.
— bichloride of mercury for, 322.
Free ammonia in water, 647.
Freeman, Miss, on education, 477.
Freienwalde, iron waters, 949.
Freiersbach, iron waters, 949.
French beans, 568.
Fresh air required per head, quantity of, 688.
Friars' balsam, 881, 919.
Friction in massage, 772.
Friedrichshall, bitter waters, 934, 935.
Fritsch and Hitzig, researches by, 93*.
Frog, nervous system of, 95, 96.
Fromage de Brie, 555.
Frontal bone, 19. Frost-bite, 1006.
Fruits, 542; — tinned, 600.
Fruit salts, 863.
Frumenty, or frumity, 559.
Frying, 608.
Fucus vesiculosus, 584.
Full-bloodedness, 235.
Fuller, Fr., on medical gymnastics, 772.
Function, localization of, 96*.
Functional diseases, 3.
Fundamental colours, 351.
— note, 355.
— tone, 263.
Fungi, 582.
Funny bone, the, 99.
Fur as a conductor of heat, 724.
Füred, bitter waters, 934.
Furunculus, 315.
Fusel oil, 570.
Fusion of impressions, 334.

G.

Gadus Morrhua, 877.
Gais, for whey-cure, 951.
Galactose, 587.
Galam butter, 591.
Galbanum, 881.
Galipea Cusparia, 840.
Gall, on phrenological theory, 97*.
Gall-bladder, 138, 142.
Gallic acid, 867.
Gall ointment, 867, 898.
Galloping consumption, 279.
Galls, preparations of, 867.
Gall-stones, 199.
— — waters for, 933, 935, 936, 939.
Galton grate, 701.
Galvanic current, 952.
Gamboge, poisoning by, 1016, 1029.
— a purgative, 862.
Game, composition of varieties of, 545.
Ganga, 902.
Ganglia, 85, 94.
— at base of brain, 88, 89.
— basal, 88.
— of cord, 96; — of spinal nerves, 92*.
Ganglion, 78.
Gangrene, 248.
— of lung, 275.
Garcina Morella, 862.
Gargles, prescriptions for, 1060.
Garlic, 594.
Garters, evils of, 475, 731.
Gaseous impurities in water, 642.
Gases of the blood, 257.
— dissolved in water, 640.
Gas stoves, 701.
Gastein, thermal springs, 926.
Gastric catarrh, bismuth for, 854.
— fever, 411, *plate 6*.
— glands, 139.
— juice, 129, 139.
— sedatives, 854.
Gastritis, 157, 180.
Gastrocnemius muscle, 74.
Gastrodynia, 181.
"Gathered" breast, 439, 516.
Geilnau, alkaline waters, 937.
Gelatin, 132, 536.
Gelsemium, morphia antidote to, 904.
— sempervirens, 903.
General debility, health resorts for, 785, 786, 787, 789, 791, 795, 796, 803.
— — mineral waters for, 925, 928, 941, 948.
— — remedies for, 818, 826, 844, 846, 877.
General diseases, 3.
General treatment of disease, 13.
Generative organs, 131.
— — diseases of, 497.
— — disorders of, waters for, 927, 928, 930, 932, 935, 937, 939, 941, 945, 948, 950.
— — female, 479.
— — remedies that act on, 893.
Genitals, itching of, 497.
Genoa, 793.
Gentiana lutea, 841.
Gentian root, 841.
Genu-valgum, 83.
German measles, 402.
— stoves, 701.
Germs, cultivation of, 392.
— in the atmosphere, 389.
— in the human body, 394.
Gerolstein, alkaline waters, 937.
Gettysburg, alkaline waters, 937.
Gibson's vermin-killer, 1028.
Giddiness, 113.
Giesshübel, alkaline waters, 937.
Gilbert's experiments, 541.
Gin, 668.
Gin-drinker's liver, 196, 671.
Ginger, 594.
— preparations of, 849.
Ginger-beer, 653.
Girasole, 571.
Girls, dress of, 472.
— education of, 476.

Girls, exercise for, 753, 771.
Glacial acetic acid, 322, 326.
— — — poisoning by, 1019.
Gland, lachrymal, 339.
— pineal, 205.
— pituitary, 205.
— thymus, 205.
— thyroid, 205.
Glanders and farcy, 422.
Glands, 875.
— blood-, 204.
— disease of, remedies for, 826, 876, 877, 892.
— ductless, 204.
— lymphatic, of mesentery, 201.
— of groin, 208.
— of Peyer, 206.
— of the bowels, 875.
— of the hair, 308.
— of the skin, 307.
— of the skin, affections of, 327.
— salivary, 137.
Glandular system, drugs which act on, 875.
Glauber's salts, 863.
Glaucoma, 375.
— eserin for, 903.
Gleet, 988.
Gleichenberg, alkaline waters, 940, 941.
Gleisweiler for grape-cure, 952.
— for whey-cure, 951.
Glengariff, 789.
Glenoid cavity, 21.
Gliadin, 561.
Globular epithelial cells, 16.
Globulin, 216.
Globus hystericus, 520.
Glomerulus, 290.
Glossopharyngeal nerve, 89, 98*.
Glottis, 262.
Glove-leather, porosity of, 727.
Gluteus maximus, 73.
— medius, 73.
— minimus, 73.
Glutin, 132, 536, 560.
Glycerine, 675.
— a laxative, 859.
— of tannic acid, 439, 867.
Glycogen, 147, 537.
Glycoses, 587.
Glycosuria, 303.
Glycyrrhiza glabra, 886.
Goat's milk, 549.
Godesberg, iron waters, 949.
Godfrey's cordial, 447.
— — poisoning by, 1025.
Goitre, 205, 210.
— exophthalmic, 211.
Golden apple, 575.
— seal, 865.
— syrup, 542, 588.
Golf exercise, 759.
Gonorrhœa, 987, 988.
Gonorrhœal rheumatism, 988.
Gooseberries, 576.
— composition of, 574.
Gooseberry wine, 677.
Goosefoot, 571, 573.
Gossypium barbadense, 591.
Goulburn, climate of, 807.
Gout, 432, 575.
— climate for, 788.
— diet for, 626.
— irregular, 433.
— remedies for, 828, 835, 889, 890.
— rheumatic, 33.
— use of water in, 890, 925, 926, 927, 928, 930, 931, 932, 935, 939, 942, 945.
Gouten, iron waters, 949.
Gouttes japonnaises, 913.
Gouty conditions, lithia in, 890.
— disorders, baths in, 741, 742.
— kidney, 296.

Goux system of closet, 720.
Graduated muscular exercises, 760.
Graham Bell, Professor, on lip reading for the dumb, 383.
Graham's experiments on osmosis, 135.
Grain, 567.
Grains of paradise, 594.
Grand Mal, 124.
Granny knot, 963.
Granular lids of eye, 369.
Granulating wounds, 968.
Granulation, 316.
Granulations, 968.
Grape-cure, 952.
— — at Meran, 797.
Grapes, 576.
— composition of, 574.
Grape-sugar, 537, 542, 587.
Grasse, 793.
Grates, construction of, 700.
Gravel, 199, 298.
— Triticum repens for, 892.
— waters for, 890, 933, 935, 936, 938, 939, 946, 947.
Graves' disease, 211.
Gray powder, 824.
Grease, in horses, 406.
Grease traps, 719.
Green-blindness, 379.
— sickness, 235.
— stick fracture, 35.
— wall-paper, poisonous, 112.
Gregory's mixture. See *Gregory's Powder.*
— pill, 860.
— powder, 844, 859.
Grey bramble, 576.
— powder, 844.
Greyness of hair, 329.
Griesbach, iron waters, 949.
Griffith's mixture, 817.
Grilling, 608.
Grits, 566.
Groats, 564.
Groin bandage, 958, 963.
Gromwell, 660.
Grosswardein, sulphur waters, 943.
Ground-nuts, composition of, 580.
Ground rice, adulteration of, 597.
Growth in children, period and rate of, 466.
— of children, standards of, 467.
Grub, 327.
Gruel, 564.
— artificial digestion of, 847.
Grünberg for grape-cure, 952.
Guaiacum, action and use of, 828.
— action on skin, 888.
— preparations of, 828.
Guarana, 663.
— bread, 663.
Guaranine, 663.
Guava, 577.
Guaza, 902.
Guggenbühl, Dr., establishment for cretins, 212.

Lateral curvature of spine, 29.
— — — exercises for, 772.
Latissimus dorsi, 71.
Latour, Cagniard de, 389.
Laudanum, 897.
Laughing, 261.
— gas, 908.
Lavatorium, 736.
Laver, 584.
Lavey, sulphur waters, 943.
Lavoisier, the chemist, 636.
Lawes' experiments, 541.
Lawn tennis as exercise, 757.
Lawson, Australia, health resort, 807.
Laxative, the term, 856.
Laxatives, list of, 856.
Laxator tympani, 357.
Lead colic, 1022.
— in water, detection of, 648.
— palsy, 122.
— poisoning by, 836, 1016, 1020, 1022.
— — thermal waters for, 925.
— preparations of, 836.
— uses of, 836.
Leamington, mineral springs, 929, 935.
Leaven, 561.
Leech bites, alum for, 869.
Leeches, mode of applying, 1051.
Leeuwenhoeck, Anton, on infusoria, 385.
— discovery of thein, 654.
Leg, arrest of bleeding from, 979.
— bandage, 958.
— body and arm exercise, 767.
— exercise, 765.
— fractures of, 52.
— muscles of, 74, *plate 2*.
— temporary treatment of fracture of, 995.
Legumin, 132, 536.
Lemon, 577, 593.
Lemonade, 653.
Lens, crystalline, of eye, 340.
Lenses, action of, 344.
Lentils, 542, 569.
— composition of, 567.

Lepidium sativum, 573.
Lepra, 321.
Leprosy, 321.
Leptandra virginica, 865.
Leptandrin, 865.
Leptus autumnalis, 325.
Lettuce, 573.
— composition of, 572.
— opium, 573.
— poisonous, *plate 10.*
Leucocytes, 213.
Leucocythæmia, 205, 235.
Leucorrhœa, 499.
Leukæmia, 235.
Leukerbad, lime waters, 946.
— thermal springs, 926, 927.
Levant worm-seed, 873.
Le Vernet, sulphur waters, 943.
Levers, 80.
Lice, 324.
Lichen, 584.
— simplex, 319, *plate 5.*
Liebenstein, iron waters, 949.
— for whey-cure, 951.
Liebenzell, thermal springs, 926, 927.
Lieberkühn's glands, 140.
Liebig, 668.
Liebig's extract of beef, 628.
— method of making beef-tea, 627.
Liebwerda, iron waters, 949.
Lientery, 185.
Life, change of, 480, 482.
Ligament, suspensory, of lens, 340.
Ligaments, 23, 24.
Light, perception of, 342.
Lightning stroke, 1004.
Ligustrum vulgare, poisoning by, 1031.
Lily of the valley, 833.
— — action of, 833.
Lime, the fruit, 577.
— juice, 593.
— — in scurvy, 237.
Lime or chalk, preparations of, 844, 876.
— or chalk, uses of, 844, 876.
— mineral waters, 923, 945.
— water, 844.
Linen, porosity of, 727.
Ling, Peter Henry, system of exercises, 760.
Lings, John, method of preserving food, 633.
Liniments, soothing, 919, 1062.
— stimulating, 917, 1061.
Linseed, infusion of, 886.
Lip, cancer of, 150.
— warty growth of, 150.
Lippen sinen (ganglion), 18.
Lippspringe, lime waters, 946, 947.
Lip-reading, 383.
Lips, cracks and fissures of, 150.
— ulcers of, 149.
Liqueurs, 668.
Liquidambar orientalis, 881.
Liquor carbonis detergens, 323.
— sanguinis, 213.
Liquorice, 886.
— powder, compound, 857.
Lisdunvarna, sulphur waters, 943, 945.
Liston's long splint, 50.
Lithia, for gout, 433, 819.
— in Saint Marco waters, 938.
— preparations of, 889.
— water, 653.
Lithospermum officinale, 660.
Liver, 131, 138, 141.
— congestion, chloride of ammonium for, 831, 843.
— degenerations of, 199.
— diseases of, 195.
— disorders, waters for, 925, 927, 930, 933, 935, 936, 942, 944, 947.
— disturbance, massage for, 773.
— enlargement of, 874.
Liver, functions of, 146.
— mercury used for, 824.
— remedies which act upon, 874.
— sluggish, baths for, 741.
— stimulants for, 865.
— torpor of, podophyllin for, 864.
— waxy, 200.
Liverpool bell-trap, 710.
Liver-spots, 322.
Lividity, 286.
Llandrindod, sulphur waters, 943.
Llandudno, 788.
Llanwrtyd, sulphur waters, 943.
Llymru, 564.
Lobelia inflata, 885.
— — poisoning by, 1031.
— — uses of, 885.
Lobenstein, iron waters, 949.
Lobster, 548. Lobules, 141.
Local diseases, 3.
Localization of function, 96*.
Loch Katrine water, 639, 645.
Lock-jaw, 126.
— — remedies for, 902, 903.
Locomotion, organs of, 79.
Locomotor ataxy, 121.
Logwood, 868.
Loka water, 639.
London porter, 678.
— stout, 678.
— water, 639.
Long-sight, 346, 377.
Loomis, Professor, on education, 477.
Looseness of bowels. See *Diarrhœa.*
— — in pregnancy, 512.
Lords and ladies, 586, *plate 12.*
— — poisoning by, 1029.
Lotions, soothing, 919, 1061.
— stimulating, 917, 1061.
Lousiness, 324.
Love-apple, 574.
Lower jaw. See *Jaw.*
Lowestoft, health resort, 785, 788.
Low fevers, serpentary for, 841.
Lucayos, 803.
Lucca, lime waters, 946.
— thermal springs, 926.
Lucifer matches, poisoning by, 1020.
Luhatschowitz, alkaline waters, 940, 941.
Lukewarm water an emetic, 851.
Lumbago, mineral waters for, 930, 945.
— neuralgic, 128.
— remedies for, 835, 893, 913, 915.
Lumbar abscess, 28.
— nerves, 91, 92, 99.
— plexus, 99; — region, 131.
— vertebra, 20, 88, 91, 92.
Lunar caustic, 870.
— — poisoning by, 1020.
Lung affections, climates for, 782, 792.
— — sea voyages for, 783.
— — Mont Dore waters for, 938.
— diseases, remedies for, 826, 834, 872.
— gangrene of, 275.
Lungs, the, 138, 252.
— bleeding from, 282.
— collapse of, 283.
— congestion of, 275.
— drugs which act on, 878.
— inflammation of, 274.
— injury of, 284.
— remedies which lessen circulation in, 883.
— stimulants to circulation in, 879
Lupuline, 841.
Lupus, 321.
Luxeuil, thermal springs, 926.
Luxor, health resort, 800.
Lycopersicum esculentum, 574.
Lying trap, 708.
Lymph, 203.
Lymphadenoma, 210.
Lymphangitis, 206.
Lymphatic glands, abscess of, 206.
— — inflammation of, 207.
— — of arm, head, and neck, 208.
— — of mesentery, 201.
— — structure of, 201.
— tissue, 16*.
— tumours, 209.
— vessels, 202.
— — inflammation of, 206.
— — of leg and groin, 208.
Lymphatics, absorbing power of, 204.
Lymphoma, 210.
Lysis in fevers, 397.

M.

Macaroni, 563.
Macaroons, 580.
Mace, 595.
Mackerel, 547.
Mackintosh cloth, 727.
Maclaren on rowing, 755.
— on training, 754.
Macula lutea of eye, 341.
Macule or spot, 313.
Madeira health resort, 783, 784, 797.
— rainfall at, 790.
— wine, 67.
Magnesia, antidote to arsenic, 841.
— — to copper, 844.
— — to mercury, 844.
— — to oxalic acid, 844.
— — to poisoning by strong acids, 844.
— carbonate of, a laxative, 869.
— preparations of, 843.
— uses of, 843.
Magnesium in human body, 534.
Mahableshwur, Indian health station, 804, 805.
Maize, 565.
— composition of, 558.
Maize arrow-root, 586.
Maizena, 566.
Malaga, health resort, 794.
— rainfall at, 790.
Malar bones, 19.
Malaria, 8, 427.
— climate for, 427, 785.
— mineral waters for, 928, 948.
— remedies for, 821, 823, 882, 913.
Malarial poisoning, iron in, 818.
— — Orezza waters for, 950.
Mal des montagnes, 680.
Male-fern root, 871.
— — use of, 871.
Malic acid, 574.
Malignant tumours, 433.
Malleoli, 23.
Malleus or hammer, 357.
Mallotus philippinensis, 872.
Mallow, spring at, 928.
Malpighi, pyramids of, 289.
Malpighian body of kidney, 290.
— bodies of spleen, 204.
Malt, 565.
— in fermentation, 666.
— liquors, 677.

Scarlet fever, 399, *plate 6*.
— runner, 568.
Schandau, iron waters, 949.
Schinznach, sulphur waters, 943.
Schlangenbad thermal springs, 926, 951.
Schleiden, cell theory of, 16.
Schmalkalden, mineral springs, 929.
Schneiderian membrane, 338.
Schoolboys, diet for, 618.
"Schott Treatment" of heart disease, 934*.
Schrœder and Dusch, 386.
Schwalbach, iron waters, 949, 950.
Schwann, cell theory of, 16.
— white substance of, 85.
Sciatic nerve, 99.
Sciatica, 128.
— vapour baths for, 739.
— remedies for, 872, 913, 915, 942, 945.
— thermal springs for, 925.
Scilly Isles, 787.
Scirrhus, 434.
Sclerosis, 118.
Sclerostoma duodenale, 175.
Sclerotic coat of eye, 339.
Scolex, 168.
Scoparin, 891.
Scorbutus, 237.
Scorpion sting, 984.
Scott's dressing, 917, 918.
Scrofula, 431.
— climate for, 785.
— mineral waters for, 928, 930, 931, 932, 938, 945.
— remedies for, 876, 889.
— sea-baths for, 739.
Scrofulous affections, cod-liver oil for, 877.
— cachexia, 4.
Scultetus bandage, 959.
Scurvy, 237.
— potash for, 819.
Sea bathing, 739.
— — for children, 739.
— baths, artificial, 739.
— cabbage, 572.
— girdle, 584.
— kale, 573.
— — composition of, 572.
— sickness, remedies for, 837, 905, 906.
— voyages in disease, 783.
— water, 646.

Seat, four-handed, 996.
— three-handed, 996.
— two-handed, 996.
— worm, 174.
Sea-weed, 584.
Sebaceous glands, 308.
— — excessive secretion of, 327.
Seborrhœa, 327.
Secale cereale, 565.
— cornutum, 565.
Second arm exercise, 762.
— body exercise, 764.
— leg exercise, 766.
Second intention, healing by, 968.
Secondaries, in syphilis, 424.
Seconds flour, 560.
Sedative mixtures, recipes for, 1059.
Sedatives, 897.
— for heart, 833.
— use of, 855.
Sedentary habits, 5.
Sedlitz, bitter waters, 934.
Seeds or sowans, 564.
Seidlitz powder, 863.
Selmi of Bologna, 599.
Selters, alkaline waters, 940, 941.
Semicircular canals, 357.
Semilunar bone, 22.
— valves, 221.

Sighing, 261.
Sight, the, 338, 342.
— defective, from age, 378.
— nerve of, 97*.
— normal or regular, 345.
— short and long, 347.
Sigmoid flexure, 130.
Silicon in human body, 534.
Silk as a conductor of heat, 724.
— porosity of, 727.
Silkworm disease, 391.
Silver, mitigated nitrate of, 870.
— nitrate of, 870.
— poisoning by, 1016, 1020.
— salts, 870.
Simla, health resort, 804.
Sinapis, 914.
— alba, 573.
— nigra, 593.
Sinks in houses, 718.
Sinus, 261; sinuses of the brain, 90.
Siren, the, 354.
Sitz bath, 741.
Skate, 547.
Skeleton, the human, 19, *plate 1*.
Skim milk, composition of, 552.
Skin, 136.
— absorption by, 310.
— care of the, 330.
— diseases of the, 313, *plates 4, 5*.
— — baths in, 740, 741.
— — electricity in, 953.
— — mineral water for, 925, 930, 931, 942, 944.
— — of eyelids, 367.
— — remedies for, 823, 881, 882, 888, 889, 913.
— drugs which act upon the, 841, 886.
— effects of exercise on the, 746.
— eruptions of the, 311.
— functions of the, 308.
— glands of the, affections of, 327.
— grafting, 1000.
— in diagnosis, 13.
— injuries to the, 329.
— of teeth, 137.
— pores of the, 733.
— remedies which redden and blister the, 914.
Skin, sensibility of the, 364.
— structure of the, 306.
— ulcers of the, 315.
Skull, fractures of, 39.
Sleep, 114.
— drugs which procure, 902, 904.
— of infants, 445.
Sleeplessness, 113, 116.
— baths in, 742.
— remedies for, 826, 833, 905, 906.
Slings, 962.
Sloke, 584.
Sloughs, 970.
Smallage, 573.
Small intestine, 139.
— intestines, absorption by, 145.
— — digestion in, 144.
Small-pox, 402.
— as altered by vaccination, 405, *pl. 7*.
— black, 404.
— confluent, 404, *plate 7*.
— deaths from, 408.
— distinct, 403.
— inoculated, 405.
— modified, 405, *plate 7*.
Smell, affections of the sense of, 366.
— nerves of, 89, 97*, 338.
— organ of, 337.
— sense of, 338.
Smelling salts, 843.
Smith, Dr. Angus, on air, 687.
— — — process for rust prevention, 711.
— Dr. Edward, on alcohol, 668.
Smoke, medicated, for chest affections, 886.
Smoker's heart, 902.
Snake bites, 985.
— — ammonia for, 843.
— — treatment of, 986.
Sneezing, 261, 366.
Snipe, 545.
Snow-blindness, 378.
— water, 644.
Snuffles, 459.
Soap a test for hard water, 639.
Soap pill, 898.
— worts, 663.
Soaps, 733.
Sobbing, 261.
Socks, 731.
Socotrine aloes, 859.
Soda, bicarbonate of, a diuretic, 890.
— permanganate of, 912.
— poisoning by, 1019.
— preparations of, 819, 843.
— sulphate of, 863.
— sulpho-carbolate of, 911.
— uses of, in disease, 819.
— water, 653.
— waters with common salt, 940.
— — iron in, 948.
— — muriated, 940.
— — simple, 936, 937.
Soda and potash, tartrate of, 863.
Soden, near Aschaffenberg, mineral springs, 929.
— (Taunus), mineral springs, 929, 932.
— for whey-cure, 951.
Sodium, bromide of, 905.
— in human body, 534.
Sœmmering's yellow spot, 341.
Soft cancer, 434.
— chancre, 987.
— palate, 336.
Softening of bone, 31.
— of hard waters, 733.
Soia hispida, 569.
Soil pipes, defects in, 713.
Solanum dulcamara, 889, *plate 12*.
— — poisoning by, 1031.
— nigrum, poisoning by, 1031.
— tuberosum, 570.
— — poisoning by, 1031.

Sole, composition of the fish, 547.
Soleus muscle, 74.
Somers Islands, health resorts, 803.
Somnambulism, 113, 116.
Sool-baths, 928.
— waters, 928.
Soothing liniments, 919.
— lotions, 919.
— medicines, evils of, 447.
— mixtures, prescriptions for, 1059.
— ointments, 919.
Soporifics, 904.
Sordes, 519.
Sore throat, 155.
Sorgho-grass, 567.

Sweat, 309.
— centre, 887.
— glands, 307.
— — excessive secretion of the, 328.
Sweating, drugs which increase, 887.
— excessive, remedies for, 843, 870, 888, 900.
— powders, 887.
Sweats of consumption, acids for, 888.
Sweet basil, 594.
— chevril, 594.
— lime, 577.
— potato, composition of, 569.
— spirit of nitre, 891.
Sweet-bread, 131, 544.
Swimming in the head, 113.
Swooning, 243.
Sycamore, 578.
Sydney, climate of, 807.
Sylvester's method of artificial respiration, 1011, *plate 17*.
Sylvius, fissure of, 90.
Symblepharon, 369.
Sympathetic nerve, 225.
— ophthalmia, 376.
— system of nerves, 98*.
— vibration, 360.
Symphysis pubis, 22.
Symptoms, subjective and objective, 8.
Syncope, 243, 991.
Synechia, anterior and posterior, 372, 374.
Synovia, 23.
Synovial membrane, 24.
— — inflammation of, 32.
— sheaths or sacs, 75.
Synovitis, 32.
Syphilis, 422.
— inherited, 425.
— mineral waters for, 942, 944, 945.
Syphilitic disease of kidney, 300.
Syphon trap, 708, 710.
Systemic circulation, 230.
Systole, 224.
Szezawnica, alkaline waters, 940.

T.

Tabes mesenterica, 165.
Table-cloths, arsenic in, 732.
Tacca oceanica, pinnatifida, 586.
Tactile corpuscles, 335.
Tæniæ or cestodes, 167, 168.
Tænia echinococcus, 168, 171, 172.
— lata, 168.
— mediocanellata, 168, 169.
— solium, 168, 170.
Tailor's muscle, 74.
Talipes calcaneus, 83.
— equinus, 82.
— valgus, 82.
— varus, 82.
Tamarind, 857.
— whey, 858.
Tamar indien, a laxative, 858.
Tamarindus indica, 857.
Tamarix mannifera, 590.
Tan (sun tan), 322.
Tangiers, health resort, 799.
Tannic acid, preparations of, 867.
Tannic acid, uses of, 867.
Tannin, 655.
— antidote to antimony, 853.
Tape-worm, 167–171.
— — prevention of, 173.
— — remedies for, 871, 873.
— — symptoms of, 171.
Tapioca, 542, 586.
— artificial digestion of, 847.
Tapotement in massage, 772.
Tapping in massage, 772.
Tar, 881.
— ointments, 918.
— uses of, 881.
Tarantula bite, 984.
Tarasp, as health resort, 785, 797.
— great spring, 934, 936.
Taraxacum Dens Leonis, 858.
Tarragon, 595.
Tarring and feathering, 310.
Tarsal bone, dislocation of a, 66.
Tarsus, the, 23.
Tartar of teeth, 153.
Tartar emetic, 851, 853.
— — poisoning by, 1020.
— — uses of, 853.
Tartaric acid, 574.
— — poisoning by, 1019.
Tartrated soda, 863.
Tartrate of soda and potash, 819.
Tasajos, 630.
Tasmania, climate of, 806.
Taste, affections of the sense of, 364.
— organ of, 336.
— sense of, 337.
Taste-buds, 337.
Taunus, lime waters, 946.
Taxus baccata, poisoning by, 1032.
T bandage, 959.
Tea, 655.
— adulteration of, 659.
— aromatic oil of, 655.
— astringent constituent of, 655.
— Bohemian, 660.
— composition of, 657.
— leaves, preparation of, 656.
— Paraguay, 659.
— value of, as a food-stuff, 657.
Teale, Pridgin, on ventilation, 695.
Teale's economizer, 700.
Tear-gland, 339.
Tear-passage, obstruction of, 370.
Teeth, 136.
— bleeding after extraction of, 152.
— care of, 153.
— (decayed) cause of headache, 111.
— painless extraction of, by cocaine, 904.
— skin of, 137.
— stopping decayed, 152.
Teething, 451.
— ailments, 459.
Teignmouth as health resort, 787.
Teinach, mineral springs, 927, 937.
Temperate climates, diet in, 620.
Temperature affected by prevailing winds, 777.
— as it affects climate, 775.
— influenced by elevation above sea-level, 777.
— in forests, 776.
— mean daily, 778.
— of mountain ranges, 777.
— of surface of sandy deserts, 775.
— of the body, 10.
— of water, 776.
— range of, 779.
— sense of, 336.
Temporal bones, 19.
Tendo Achillis, 75.
Tendons and bursæ, diseases of, 77.
— injuries of, 79.
— structure and functions of, 67.
Teneriffe as health resort, 783, 798.

Tenesmus, 186.
Tenningaring, climate of, 807.
Tennis-elbow, 757.
Tensor tympani muscle, 357.
Tepidarium, 736.
Tepid bath, temperature of, 734.
— baths, 735.
Teplitz, thermal springs, 926, 927.
Terebene, 913.
— for inhalation, 883.
Terminal organ (nerves), 86.
Terminals, electric, 953.
Terra Japonica, 867.
Terrapin, 549.
Tertian ague, 428.
Tertiary symptoms in syphilis, 424.
Tetanus (lockjaw), 126.
— — remedies for, 903.
— anti-toxin treatment of, 955*.
Tetany, 127.
Tetter, brawny, 319.
— diffuse dry, 319, *plate 5.*
— moist, 318, *plate 4.*
— pustular, 319, *plate 5.*
Thallin, 822.
Thea assamica, 656.
— bohea, 655.
— other varieties, 655.
Thebaia, 897.
Thein, 654.
Theobroma Cacao, 661.
Theobromin, 654.
Therapeutics, 810.
Thermæ Silvestres, 925.
Thermal springs, 924, 926.
Thermia, mineral springs, 929.
Thermometer, 9.
— clinical, 10.
Thigh bone, 23.
— — dislocation of, 61.
— — temporary treatment of fracture of, 994.
— fractures of, 48.
— muscles of, 73.
Third arm exercise, 762.
— body exercise, 765.
— leg exercise, 766.
Thirds flour, 560.
Thirlmere water, 645.
Thirst, 146.
Thoracic duct, 145, 202.
Thorax, 20.
Thorburn, Dr., on education of girls, 477.
Thorn-apple, 885, 900, *plate 12.*
— — poisoning by, 1028.
Thread-worm, 167, 174.
Thread-worms, remedies for, 871.
— — quassia for, 841.
Three-day fever, 414.
Three-handed seat, 996.
Throat, clergyman's sore, 287.
— diseases of, 154.
— relaxed, 157.
— scalds of, 1002.
— sore, 155.
Thrombosis, 246.
Thrombus, 216.
Thrush, 149, 460.
— on genitals, 497.
— sulphurous acid for, 912.
Thumb, bandage for, 957.
— dislocation of, 61.
— and fingers, dislocation of, 61.
— muscles of, 72, 73.
Thyma Serpyllum, 594.
— vulgaris, 594.
Thyme, 594.
Thymol, 913.
— oil of, 883.
— — an antiseptic, 883.
Thymus gland, 205, 544.
Thyroid cartilage, 250, 262.
— gland, 205, 544.
Thyroid gland, diseases of, 210.
— — use as remedy, 954*.
Tibia or shin-bone, 23.
Tibial arteries, 228.
— nerves, 100.
Tic douloureux, 127.
— — butylchloral hydrate with gelsemium for, 905.
Ticks, 984.
Tic-polonga, 985.
Tidal air, 256.
Tiger snake, 985.
Tight lacing, 141.
— — cause of dyspepsia, 179.
Tiglium-oil, a drastic purgative, 861.
Tinea circinata, 326.
— favosa, 326.
— or ringworm, 326.
— sycosis, 326.
— tonsurans, 326, *plate 4.*
Tinned fruits, 600.
— meats, 632.
— vegetables, 600.
Tissue, adenoid, 201.
— adipose, or fat, 17.
— cellular, or areolar, 16*.
— connective, 15*.
— mucous, 17.
— white fibrous, 16*.
— yellow elastic, 16*.
Tissue-forming material in various foods, 596.
Tobacco, 901.
— amblyopia, 902.
— blindness, 902.
— poisoning by, 902, 1031.
— provokes dyspepsia, 178.
— smoking, evil effects of, 902.
Tobelbad, thermal springs, 926.
Tobin's inlet tubes, 696.
Toe nail, ingrowing, 330.
Toes, dislocation of, 67.
— muscles of, 74, 75.
— supernumerary, 84.
Tois-le-mois, 542.
Tokay, 674.
Tomato, 574.
— composition of, 574.
Tongue, the, 136, 336.
— accidental bites, 151.
— appearance of, in disease, 12.
— cancer of, 150.
— cracked, 150.
— furred, 12.
— inflammation of, 150.
— strawberry, 12.
— tied, at birth, 458.
— tumour under, 150.
— ulcers of, 150.
Tonicity of muscle, 69.
Tonics, acid, 841.
— blood, 817.
— heart, 830.
— nerve, 895.
— prescriptions for, 1053.
Tonic spasm, 126.
Tönnisstein, alkaline waters, 940.
Tonsil, 136.
Tonsillitis, 155.
Tonsils, inflammation of, 155.
— chronic enlargement of, 156.
Toothache, 151.
— remedies for, 911.
Tooth powders, recipes for, 1061.
Tooth rash, 320.
Toowoomba, climate of, 807.
Töplitz Warasdin, sulphur waters, 943.
Tormina, 186.
Torpid liver, mineral waters for, 863.
Torquay as health resort, 281, 784, 787.
Tortilla, 506.
Touch, 335.
— affections of the sense of, 364.
Touch-bodies, 335.
— corpuscles, 335.
Tourniquets, 980, *plate 16.*
Tous-les-mois, 586.
— — — starch granules, 598.
Towel bath, 735.
Toxicology, 1014.
Trachea, 250.
Tracheitis, 270.
Tracheotomy, 262, 270, 1012.
Trachoma, 369.
Tragopogon porrifolius, 572.
Training, diet for, 621.
— Maclaren on, 754.
— system in Cambridge, 622.
Trance, 521.
Transverse processes, 20.
Trap for sewage, varieties of, 708–710.
Trapezium bone, 22.
Trapezius muscle, 71.
Trapezoid bone, 22.
Traps, bad forms of, 710.
— for grease, 719.
— ventilation of, 710, *plate 9.*
Traumatic fever, 991.
Treacle, 542, 588.
Treatment of disease, 13.
— temporary, of fractures, 993, *plate 15.*
Treeves, Mr., on clothing, 730.
Trematode worms, 168.
Tremor, 121.

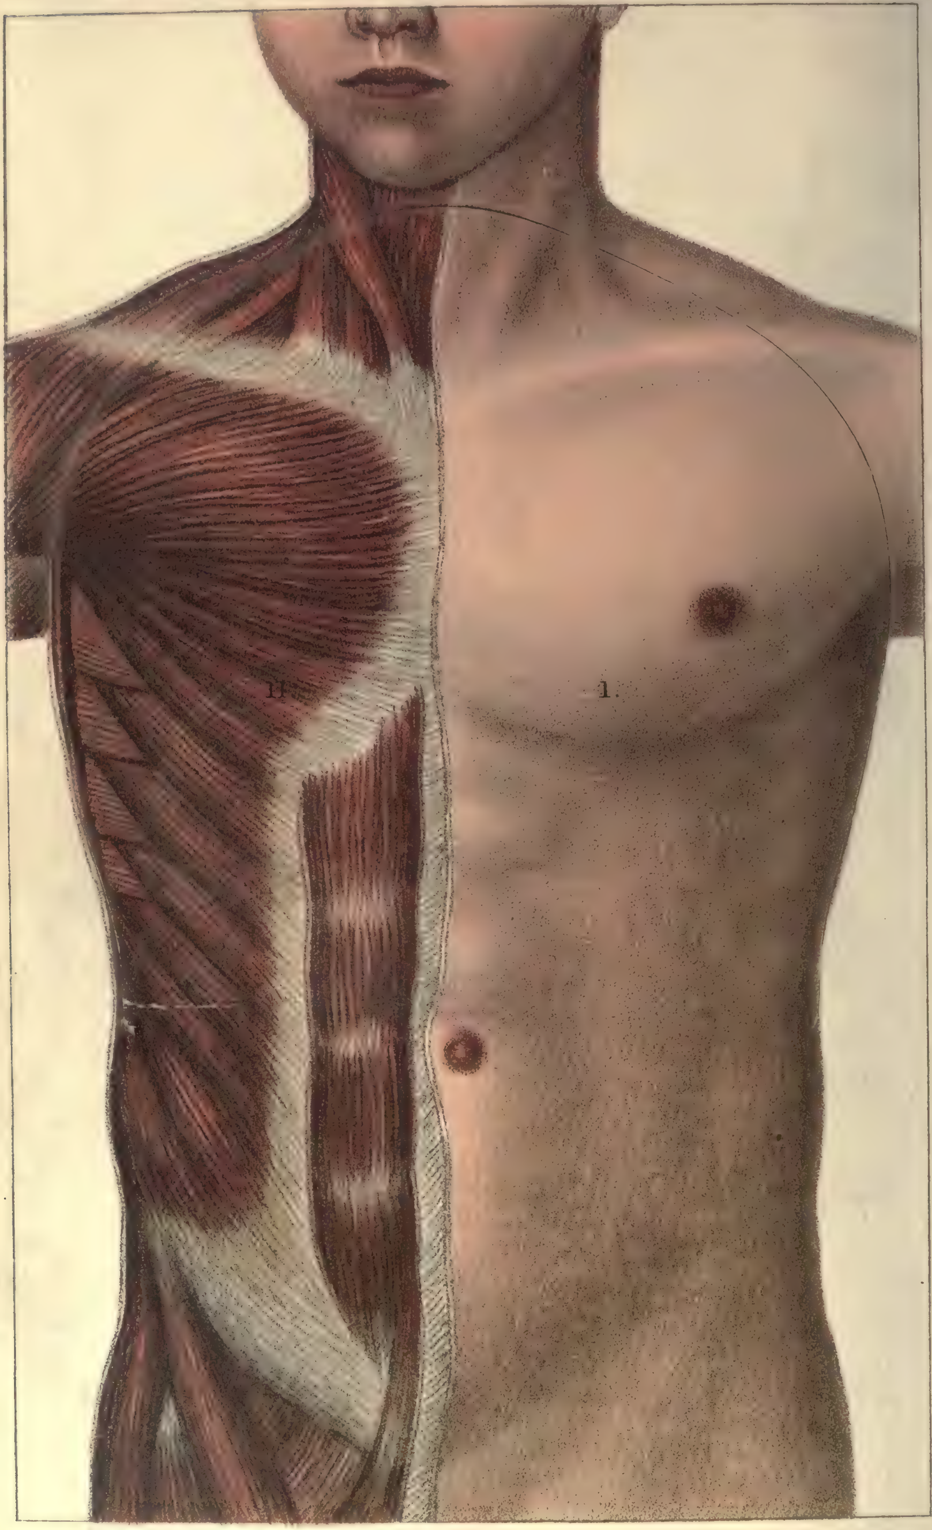
DISSECTION OF THE CHEST AND CONTENTS OF THE CHEST CAVITY.

Plate [illegible]



THE HUMAN BODY.

DISSECTION OF THE CHEST AND CONTENTS OF THE CHEST CAVITY.

1 represents the skin surface before dissection.

2 shows what is seen when the skin and underlying fat have been removed, namely, the great muscles of the chest wall.

3 is a representation of what is revealed when the chest wall down to the ribs and upper part of the abdominal wall have been removed. The figure is placed on the breast-bone, and the ribs and intercostal muscles are seen, as well as the contents of the upper part of the abdomen.

4 is the upper lobe of the right lung,

4A is placed on the middle lobe,

4B is placed on the lower lobe.

5 is the upper lobe of the left lung, 5A the lower lobe.

6 is placed on the left ventricle of the heart,

7 is on the left auricle of the heart.

8 is the arch of the aorta, and 9 on its branches to the head and neck.

10 is placed on the great veins going to the right side of the heart from the head and neck.

11 represents what is seen when the lung is cut into. The figure is placed near branches of the main bronchial tubes.

12 is on the diaphragm.

13 is on the liver, and 14 on the stomach.

H is on the larynx, and K on the thyroid gland.

The parts marked 1, 2, 3 speak for themselves. It will be observed that when the front wall of the chest is dissected off down to the bones, and the dissection carried so as to include the upper part of the abdominal wall, that the liver and stomach are seen to lie more or less under cover of the ribs, the liver lying mainly to the right side, but projecting beyond the middle line to the left, so that a finger pressed on the abdominal wall just at the end of the breast-bone would press on the liver.

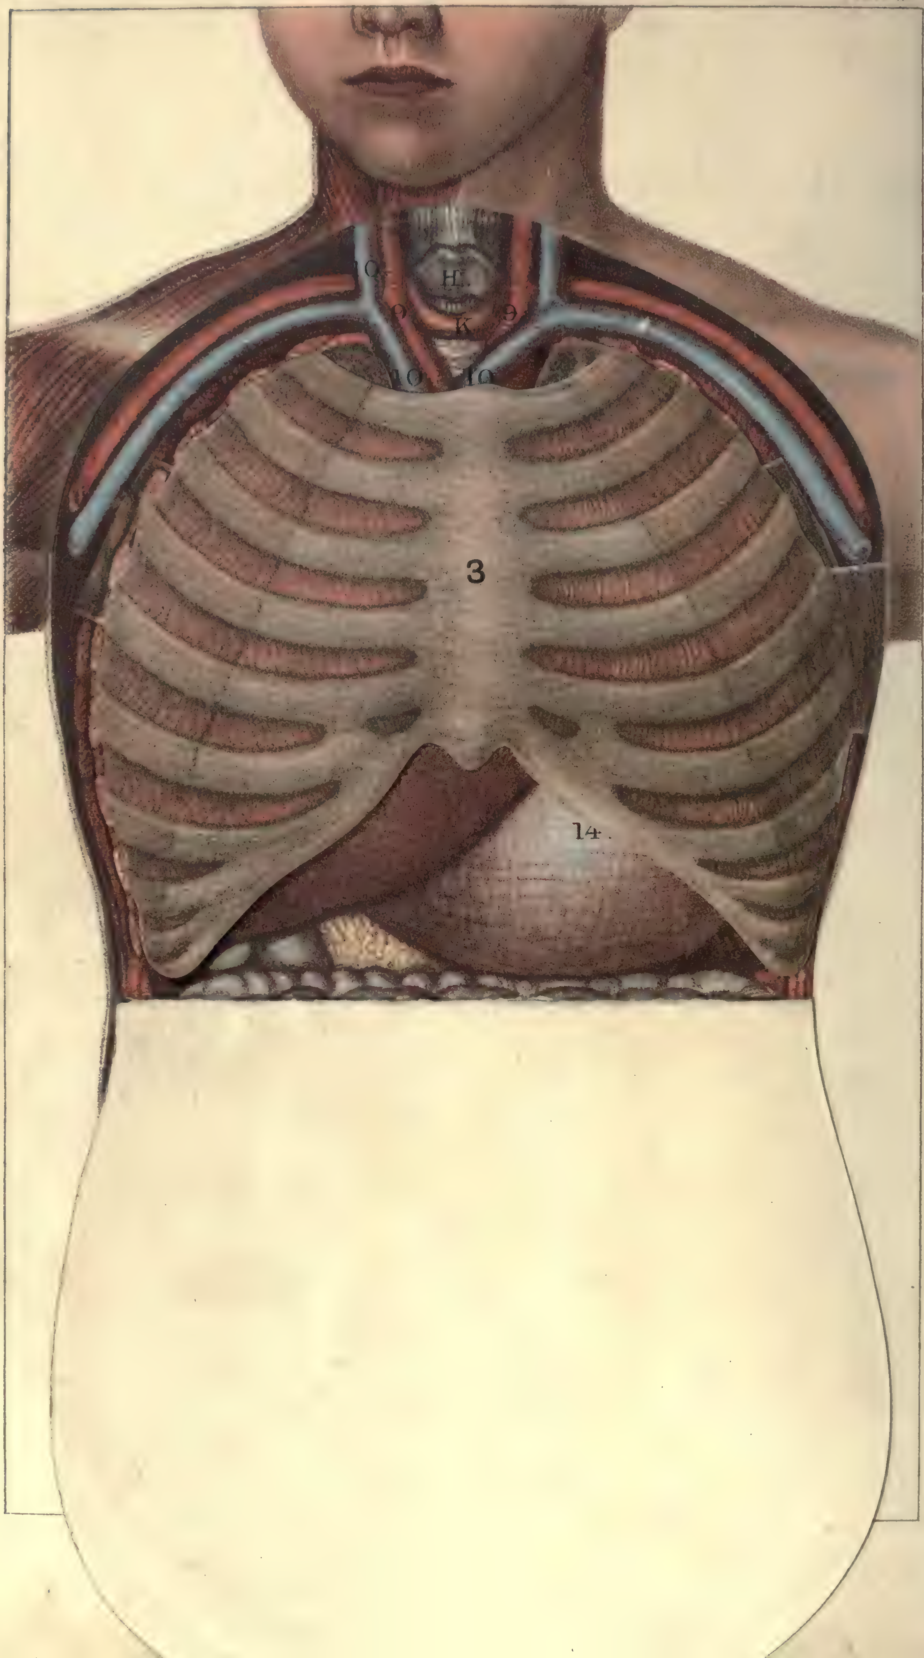
When the whole bony wall of the chest has been removed (represented by lifting the flap 3) it is seen that the lungs occupy the main portion of the chest cavity, the heart lying between, largely overlapped by the lungs, specially the left, and that the heart lies obliquely, its apex being directed to the left side. The position of the great artery arising from the heart and the great veins passing to it, and the branches of these to head and neck and upper limbs, are well shown. The plate also shows how the diaphragm separates the cavity of the chest from that of the abdomen, and how the liver and stomach lie under cover of the diaphragm. The lower part of this plate just indicates the transverse portion of the large bowel below the liver and lower border of the stomach. The plate representing the dissection of the abdomen shows this more fully.

For full information regarding the Apparatus of the Circulation, see page 218.

THE HUMAN BODY.

DISSECTION OF THE CHEST AND CONTENTS OF THE CHEST CAVITY.

Plate II



THE HUMAN BODY.

DISSECTION OF THE CHEST AND CONTENTS OF THE CHEST CAVITY.

1 represents the skin surface before dissection.

2 shows what is seen when the skin and underlying fat have been removed, namely, the great muscles of the chest wall.

3 is a representation of what is revealed when the chest wall down to the ribs and upper part of the abdominal wall have been removed. The figure is placed on the breast-bone, and the ribs and intercostal muscles are seen, as well as the contents of the upper part of the abdomen.

4 is the upper lobe of the right lung,

4A is placed on the middle lobe,

4B is placed on the lower lobe.

5 is the upper lobe of the left lung, 5A the lower lobe.

6 is placed on the left ventricle of the heart,

7 is on the left auricle of the heart.

8 is the arch of the aorta, and 9 on its branches to the head and neck.

10 is placed on the great veins going to the right side of the heart from the head and neck.

11 represents what is seen when the lung is cut into. The figure is placed near branches of the main bronchial tubes.

12 is on the diaphragm.

13 is on the liver, and 14 on the stomach.

H is on the larynx, and K on the thyroid gland.

The parts marked 1, 2, 3 speak for themselves. It will be observed that when the front wall of the chest is dissected off down to the bones, and the dissection carried so as to include the upper part of the abdominal wall, that the liver and stomach are seen to lie more or less under cover of the ribs, the liver lying mainly to the right side, but projecting beyond the middle line to the left, so that a finger pressed on the abdominal wall just at the end of the breast-bone would press on the liver.

When the whole bony wall of the chest has been removed (represented by lifting the flap 3) it is seen that the lungs occupy the main portion of the chest cavity, the heart lying between, largely overlapped by the lungs, specially the left, and that the heart lies obliquely, its apex being directed to the left side. The position of the great artery arising from the heart and the great veins passing to it, and the branches of these to head and neck and upper limbs, are well shown. The plate also shows how the diaphragm separates the cavity of the chest from that of the abdomen, and how the liver and stomach lie under cover of the diaphragm. The lower part of this plate just indicates the transverse portion of the large bowel below the liver and lower border of the stomach. The plate representing the dissection of the abdomen shows this more fully.

For full information regarding the Apparatus of the Circulation, see page 218.

THE HUMAN BODY.

DISSECTION OF THE ABDOMEN AND ITS CONTENTS.

1 represents the skin of the abdomen before dissection.

2 shows the muscles of the abdominal wall when the skin and underlying fat have been dissected off.

3 The stomach. 4 The liver. 5 The curve of the first part of the small intestine—duodenum.

6, 7, 8 are on different parts of the pancreas.

9 is on the spleen.

10 is surrounded by coils of the small intestine.

11A, 11B, 11C the ascending, transverse, and descending parts of the large bowel.

11D is on the termination of the large bowel, the rectum.

12 is placed on the upper part of the bladder.

13 is on the left and 14 on the right kidney, and 15 on the ureters leading from them to the bladder.

16 is on the ascending vena cava, 17 on the descending aorta.

This plate shows that when the front wall of the abdomen has been removed the main portion of the cavity is seen to be occupied by the coils of the small intestine, the large intestine lying somewhat behind and passing up on the right side to the lower border of the liver, then bending to pass across to the left side, there again bending to pass downward towards the left groin, where it performs an S-like turn upon itself, and then continues straight to its outlet. The plate shows the liver on the upper right side of the cavity, and the greater curvature of the stomach on the upper left side, the spleen lying close to the left border of the stomach.

If the lower edge of the liver and stomach be slightly turned up, the commencement of the small intestine is seen sweeping in a curve from the narrow end of the stomach, and in the bend thus formed lies the large end of the pancreas, which, when the stomach is distended, lies behind that organ.

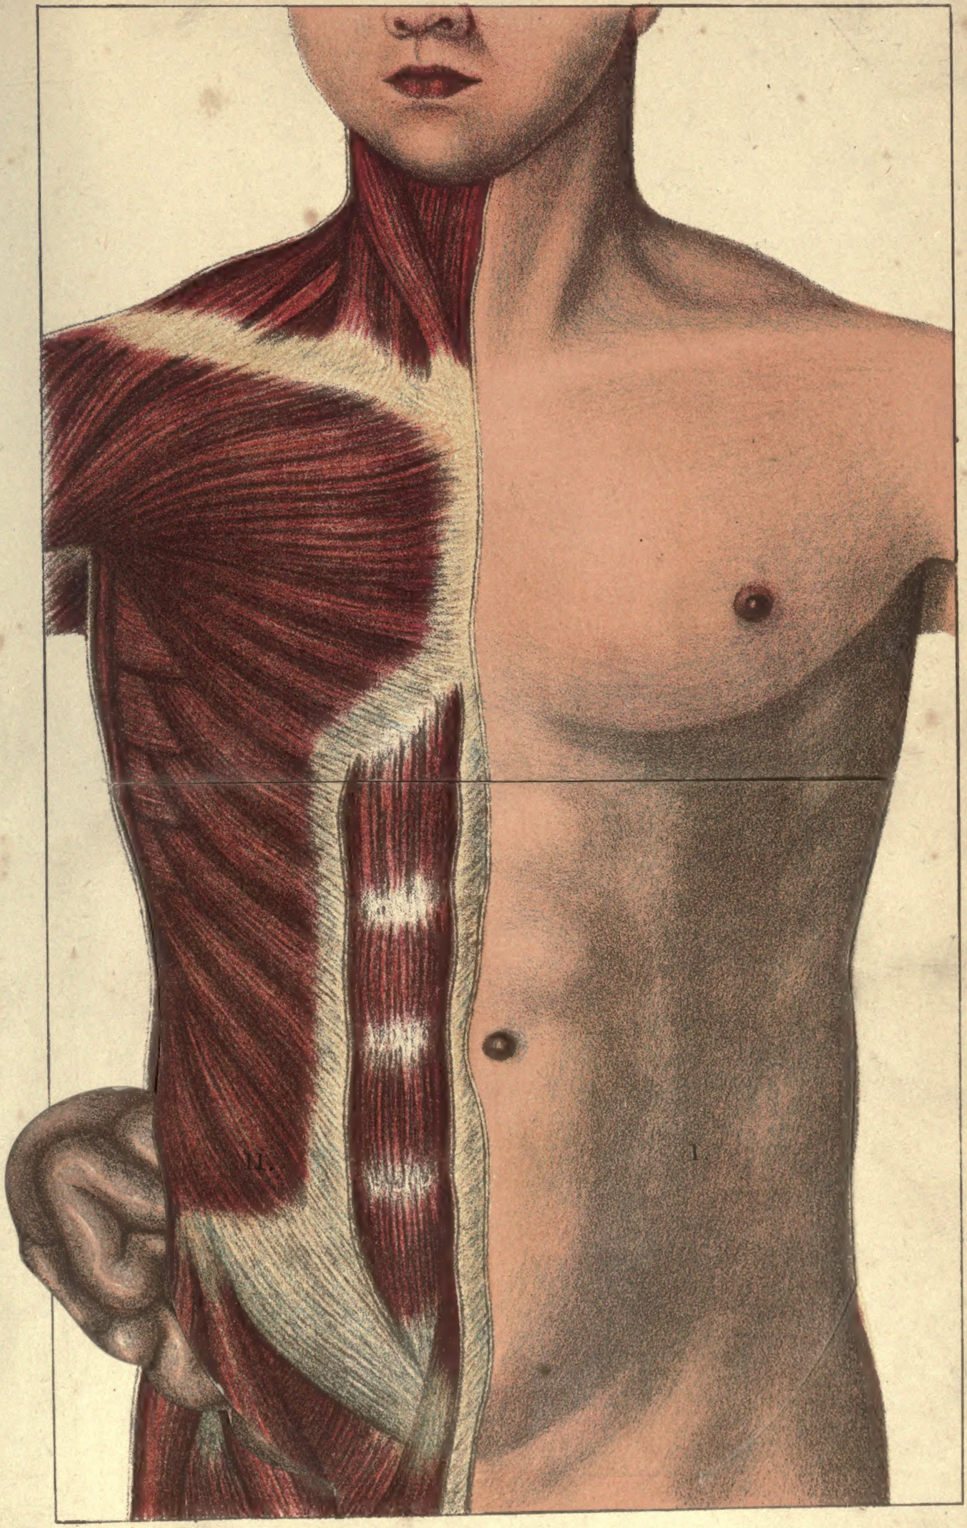
If the intestines be removed the kidneys are seen to lie close to the back wall of the cavity, and the ducts (ureters) leading from them to the bladder are shown. The bladder is represented distended, so that it peeps up above the level of the front part of the haunch bone.

For full information regarding the Digestive System, see page 129.

THE HUMAN BODY.

DISSECTION OF THE ABDOMEN AND ITS CONTENTS.

Plate XXI



THE HUMAN BODY.

DISSECTION OF THE ABDOMEN AND ITS CONTENTS.

1 represents the skin of the abdomen before dissection.

2 shows the muscles of the abdominal wall when the skin and underlying fat have been dissected off.

3 The stomach. 4 The liver. 5 The curve of the first part of the small intestine—duodenum.

6, 7, 8 are on different parts of the pancreas.

9 is on the spleen.

10 is surrounded by coils of the small intestine.

11A, 11B, 11C the ascending, transverse, and descending parts of the large bowel.

11D is on the termination of the large bowel, the rectum.

12 is placed on the upper part of the bladder.

13 is on the left and 14 on the right kidney, and 15 on the ureters leading from them to the bladder.

16 is on the ascending vena cava, 17 on the descending aorta.

This plate shows that when the front wall of the abdomen has been removed the main portion of the cavity is seen to be occupied by the coils of the small intestine, the large intestine lying somewhat behind and passing up on the right side to the lower border of the liver, then bending to pass across to the left side, there again bending to pass downward towards the left groin, where it performs an S-like turn upon itself, and then continues straight to its outlet. The plate shows the liver on the upper right side of the cavity, and the greater curvature of the stomach on the upper left side, the spleen lying close to the left border of the stomach.

If the lower edge of the liver and stomach be slightly turned up, the commencement of the small intestine is seen sweeping in a curve from the narrow end of the stomach, and in the bend thus formed lies the large end of the pancreas, which, when the stomach is distended, lies behind that organ.

If the intestines be removed the kidneys are seen to lie close to the back wall of the cavity, and the ducts (ureters) leading from them to the bladder are shown. The bladder is represented distended, so that it peeps up above the level of the front part of the haunch bone.
